Two instances are related which throw a strong side light on Brown and his peculiar mental make-up. They occurred as follows: A medical student was sick of a fever and under the care of an eminent practitioner in Edinburgh who was treating the case in the usual antiphlogistic manner. This treatment was severe, and the patient was not improving, when another student, who was an ardent Brunonian, tampered with the nurse and induced her to administer strong stimulants. The effect was so favorable that Dr. Duncan, who had charge of the case, thought that his patient had recovered. The patient, however, relapsed, and the great Brown was again consulted clandestinely, and more stimulants were surreptitiously administered. The patient finally got well. This was hailed by the Brunonians as a great triumph. But it nearly led to the prosecution and punishment of their leader, whose duplicity served to deepen the dislike and distrust with which his contemporaries regarded him.

Another case of fever about this time having been submitted to the Brunonian treatment, openly and fully, turned out badly, and the patient died. An autopsy was held at which Brown was present. It appeared that the body had undergone no putrefactive changes, a fact upon which the leader of the Brunonians dwelt in triumph, saying, "Gentlemen, I appeal to you if we may not consider this as a clear proof of the propriety of our practice."

This incident is of especial interest as showing the foggy methods of reasoning and the want of a sense of humor which have ever distinguished the system makers in medicine. It shows, also, how this class of theorizers loved then as now to make the worse appear the better reason.

Quoting Richardson again, I will give an epitome of the so-called Brunonian theory.

(A) In all states of life men and other animals differ from themselves in their dead state, or from any other inanimate matter in this property alone; they may be affected by external agents, as well as by internal, or functions peculiar to themselves, in such a manner that the phenomena peculiar to the living state can be produced. This proposition extends to everything that is vital in nature, and therefore applies to vegetables.

(B) The external agents are reducible to heat, diet, and other substances taken into the stomach, the blood, the fluids secreted from the blood, and the air.

(C) The internal agents, or functions of the body itself, namely muscular contraction, sense or perception, energy of the brain in thinking and in exciting emotion or passion produce the same effects.

(D) If the property which distinguishes living from dead matter or the operation of either of the two sets of powers be withdrawn, life ceases. Nothing else than the presence of these is necessary to life.

(E) The property on which both these sets of powers act may be termed "excitability" and the powers themselves "exciting powers."

(F) The effects common to all the exciting powers are sense, motion, mental exertion, and passion.

(G) The effect of the exciting powers acting upon the excitability may be denominated "excitement."

(H) Some of the exciting powers act by impulse. They may be denominated "stimulants" or "stimuli," which may be universal or local.

(I) What excitability is, or in what manner it is affected by the exciting powers, we do not know.

But whatever it may be, whether a quality or a substance, a *certain portion is assigned to every being upon the commencement of its living state.* (Italics mine.) The quantity of energy is different in different animals, and in the same animals at different times.

(J) The general powers produce all the phenomena of life, and the only operation by which they do so is stimulant. It follows, therefore, that the whole phenomena of life, every state and degree of health and disease, are also owing to stimulus and no other cause.

(K) Excitement, the effect of the exciting powers, the true cause of life, is within certain boundaries proportional to the degree of stimulus. The degree of stimulus, when moderate, produces health; in a higher degree it gives occasion to diseases of excessive stimulus. In a lower degree or excessively weak, it induces those diseases which depend upon a deficiency of stimulus.

(L) Every age and every constitution, if the excitement be properly directed, has its appropriate degree of vigor.

(M) Life must be considered as a *forced state.* The body lives as long as the exciting powers act upon it through its excitability. If the exciting powers are removed from it death is as certain as it would be if the excitability itself were withdrawn.

(N) The seat of excitability in the living body is the nervous matter and muscular solids to which the appellation of nervous system may be given. In this the excitability is *inherent,* but is not different in different parts of its seat.

(O) Everyone of the exciting powers always affects some one part more than any other, and different powers affect different parts in this unequal manner. The affected part is generally that to which the power is directly applied.

The above is said by Richardson to be the epitome of the tenets of his doctrine, made by Brown himself. They were officially promulgated by Brown in the "Elementæ Medicinæ," published in 1780. In that year Brown was elected for the second time President of the Royal Medical Society of Edinburgh, and this period may be called the zenith of his career.

In commenting on the above extract of the Brunonian Theory Richardson says: "In this purely mechanical day, when nothing is allowed that is not experimentally illustrated, the hypothesis of Brown may seem, and I doubt not does seem, a mere fancy. Yet when it is candidly considered it is very much more. As an abstract reading of vital phenomena, it is indeed a most ingenious exposition and shows that its author was a man gifted with curious insight, a man of genius of a very high order. To this day we have not come much nearer to the true solution of the great question of life than the hypothetical solution which he advanced.

"Had Brown been content to put forth the hypothesis which bears his name, he would have had no serious quarrel or opposition. But to make a long story short, he must turn his alleged great discovery to a practical account. He must deduce from it a system of practice, from which he could obtain wealth and worldly honor." Richardson adds sententiously: "How many men of genius in medicine have split upon this deceitful rock! Those only can tell best who have read the history of medicine with most care, and they know that there is not one instance on record of a physician of great original genius ever having been a physician esteemed great as a healer (in his lifetime) by the world at large." "With a certain kind of enthusiasm, which his words and arguments sometimes show to be inconclusive even to himself, Brown tried to adapt his hypothesis to practice. He argued that as in some persons there is implanted a certain measure of excitability, which is dead unless it be called into excitement, or life, by an exciting power or stimulant, so the changes or phenomena which we see in disease are due entirely to errors of function existing between the excitability and the exciting powers. If the exciting powers do not call the excitability into action, there is set up a want of excitement or deficient life, a direct debility. If, on the other hand, the exciting powers are brought excessively into action, there is an exhaustion of the stock of excitability and indirect debility follows. In the end, in cases where life is most prolonged, the excitability is at last exhausted and then, as the exciting powers have nothing left to act upon, there is final death. But during life, when in its prime, a large primitive stock of excitability may be knocked out of the body by an exciting power or stimulus, instantly, as by a blow, more slowly but still rapidly, as by the too frequently repeated stimulus of wine.

"On these principles he divided diseases into two great classes, the sthenic and asthenic. Disease marked by over-excitement and induced by action of the exciting powers he called sthenic. Disease marked by feeble excitement, whether induced by deficient excitability, or by feebleness of the exciting powers, he called asthenic. These two terms which he invented for his system still remain in common acceptation.

"Taking death then as the type of the final disease, Brown insisted that every disease is an approach to death, a result either of exhausted excitability or of deficient stimulus, in either case a result of debility. To make this hypothesis bear more fully on practice he went a degree further. He taught that where the excitability is wasted by any one stimulus there is still a reserve of it capable of being acted on by another stimulus, and to show the applicability of this view he cited the case of a gentleman who, under intense literary labor, supported himself for forty hours with alacrity by frequently changing his stimulus. The first stimulus was a good dinner; then work with a glass of wine every hour for ten hours, then food, nourishing, but sparing in quantity, then work again, with punch, not too strong. But sleep coming on under the pressure he changed his stimulus. The punch was replaced by opium, more excitability was thus called out. In forty hours the work was completed and, by continuation for five hours longer, the proofs were read and corrected. The succession of stimuli in this case was first food, next the stimulus of the intellectual faculties, then wine, then the food varied, then punch, then opium, then punch and conversation.

With this extensive range of action by the employment of varied stimuli, Brown was able very easily to construct a speculative system of therapeutics and régime, which necessarily had its fascinations.

I quote a prescription of Brown's for a hypochondriac: "For breakfast toast and rich soup made on a slow fire. A walk before breakfast and a good deal after it; a glass of wine in the forenoon, *from time to time;* good broth or soup to dinner, with meat of any kind he likes, but always the

most nourishing; several glasses of port or punch to be taken after dinner, till some enlivening effect is perceived from them, and a dram (of whiskey?) after everything heavy. One hour and a half after dinner, another walk; between tea and supper a game with cheerful company at cards or any other play, never too prolonged, a little light reading, jocose, humorous company, avoiding that of popular Presbyterian ministers and their admirers and all hypocrites and thieves of every description. Lastly, the company of amiable, handsome, and delightful young women, and an enlivening glass."

been written by one Robert Jones, M.D., a pupil of his. He also wrote and published anonymously in 1787 a book "On the Principles of the Old System of Physic. By a Gentleman Conversant on the Subject." This was a covert and ungentlemanly attack on the views of Cullen, his quondam, friend and benefactor, whom to the last he never forgave. He left a large family, two sons (Baas says four sons) and four daughters. Contributions for their support poured in from foreign countries, and the students in Scotland and Padua went into mourning for him. He was much more famous dead

JOANNI BRUNONI, M D.

HANC TABULAM, UT SUÆ IN PRÆCEPTOREM REVERENTIÆ MONUMENTUM DICAT ILLIUS AMICUS ET DISCIPULUS,

SAMUEL LYNCH.

An enthusiastic pupil of his, named Samuel Lynch, constructed a sort of barometer of disease, of which I have been able to procure a copy, which I will explain and then pass around.

About 1780 Brown was imprisoned for debt, and delivered lectures during his incarceration, until relieved by a present of one hundred pounds from an unknown friend. Not being able to make things go, financially speaking, in Edinburgh, he finally gave it up and went to London in 1786, where he was again imprisoned for debt. However, he was bailed out by friends and had started to make a living, when, in October, 1788, after taking, as was his custom, a large dose of laudanum, on going to bed he was seized with apoplexy from which he died. Just before his unfortunate end he had narrowly missed a call to Berlin and another to Padua as a teacher, the scale having been turned against him by his dissipated habits.

The best thing that we know about this peculiar man was that he once refused a large sum of money to allow a speculator to bring out an "exciting pill" bearing his name, and that, too, when he was oppressed by debt, and in the midst of dire financial distress. He was vain to weakness. He, himself, wrote and published in 1781 a book supporting the Brunonian system, alleged to have

than alive. He has been called the Paracelsus of Scotland. The comparison is by no means entirely inept. Both showed remarkable courage and good fighting qualities in attacking the moss-covered errors of their day; both made their mark which will never be entirely effaced from medical history; both blazed the way for the advance of scientific truth; both builded better than they knew, and both finally died in poverty and neglect from the abuse of alcohol.

That a rational man should not only have attempted to build up, but actually did build up a theory of the etiology of all human diseases and their treatment upon such facts, which no one disputes, as that alcohol and opium, if taken in sufficient quantities, will allay pain and stimulate the imagination, would be quite incredible did not every student of the history of medicine know that the various systems and sects in the practice of medicine have been built up and defended on even more ephemeral grounds than these.

That these sects and systems of medicine founded on assumption should lead to bitter feuds among their adherents and opponents was only to be expected, as most men will fight to the death for their opinions and let the facts take care of themselves. So the Brunonians and the Cullenites

fought violently with tongues, fists, and cudgels, and challenged each other to duels. The dueling seems to have been stopped only when the Royal Medical Society of Edinburgh voted to dismiss any member who engaged in a duel. Probably in resentment for some strictures upon their belief or practice 400 students of the University of Göttenberg, ardent Brunonians, led by an enthusiastic young professor, armed themselves with cudgels and after indulging in breaking windows and other riotous demonstrations overcame the police and seized the town house. It took some days to restore order in the university.

Twenty years in the university working as a "grinder" was passed before Brown got his degree in medicine. It scarcely seems wonderful that he was a theorizer and a pedant rather than a physician, for he never seems to have enjoyed much private practice.

In the light of the history of medical systems and theories we may say that the fact that the new system did not immediately "take" with the laity seems perhaps rather strange. But we must remember that it takes time for the introduction of any new system in medicine. Probably if Brown had not been so dissipated in habits and pugnacious in disposition, and had not drunk himself to death at 52, he would have lived to see his hopes of wealth and worldly position realized in spite of his follies, his inordinate vanity, and the weakness of his character. One principal reason for the comparatively short duration of the Brunonian system was evidently its simplicity. All diagnosis, all pathology, and practically all infections were disregarded by it. A patient either felt well and seemed up to the standard (30° to 50° in the scale) or he did not. In the first alternative he was to receive stimulation to preserve his excitation in equilibrium, and in the second alternative he was to be stimulated to restore the equilibrium of his excitation. The vulgar mind does not approve of any system of medicine that it can understand. As Mark Twain said, his auditors always believed him implicitly, except when he told them the truth. So, in medicine, simple and easily understood doctrines do not "take" well for any considerable time whether they be true or not.

Gross says that the Brunonian system had extensive sway for only twenty-five years (mostly after its author's death). Yet after all is said and done, it is only ideas that are immortal, and it seems to me quite safe to assert that some of Brown's ideas are still exceedingly potent in the minds not alone of the laity, but of the profession. To be sure the consumption of alcoholic beverages, the sheet-anchor of his system, has been steadily decreasing since Brown's day, and this decrease has been notable during the past few years, largely because the white light of science has been turned upon the study of the effect of alcohol upon the human body, with the result that the enormous harm which this drug has entailed upon mankind can no longer be doubted by any fair-minded person. So long, however, as authoritative or fiat medicine held sway, the scientific investigation of the fundamental questions of human alimentation was never properly undertaken. A total abstainer a generation or two ago, wishing to effect an insurance upon his life was charged an extra premium, because the life insurance doctors esteemed a man who did not sustain his vital powers by alcoholic stimulation a risk inferior to the average. This feeling was quite probably due to Brown's teaching. In our day those who have most thoroughly investigated the question of diet believe that a preponderance of all human ailments is due to overeating and improper eating. Overfeeding the sick as well as the healthy in order to keep their "strength up" is another fruit of the Brunonian theory. Mankind is practically the only animal that eats when he is sick, and he would not as a general thing eat during illness were it not that he feels (his doctor and his nurse and his family urging him on), that he must eat to keep his "strength up" if he wants to throw off his disease. Every one assumes apparently that if some food gives strength more food will give greater strength. Many a patient is fed to death with the doctor's concurrence and consent. And yet we do not study diet, but spend our energies in trying to learn how to cure the evil effects of an improper diet. In this respect we still have the cart before the horse.

Another of the errors promulgated by Brown and many others and still firmly believed by many of the profession and the laity is that "a certain portion of excitability (*i.e.* vital principle, vital energy, or strength) is assigned to every being upon the commencement of its living state." In other words so much energy is given to each human being or animal at birth. This cannot be augmented, it may be husbanded, but cannot be increased. This is a fundamental and foolish error which is one of the main props of fiat medicine.

All the sects in medicine assume also that the physician, not nature, cures the disease. This second fundamental error is another main prop of fiat medicine. In regard to this popular fallacy, sedulously cultivated, of course, by the system makers, Voltaire, I believe it was, said that "the physician amuses the patient, while nature cures the disease." The third leg of the tripod of fallacy upon which all these superstructures of authoritative medicine are built up is that there is a remedy for every disease if we are only astute enough to find it.

If one admits the truth of these three postulates, what is more natural than that an ambitious theorizer should expect to achieve immortality by evolving a system of medicine that will work? Unfortunately our profession has not yet overcome its tendency to worship theories and systems, to "make tithes of mint and anise and cummin and to neglect the weightier matters of the law." Gross says, "As fast as one delusion enslaving the professional mind disappears another springs up to take its place, and thus it will probably ever be." This was written forty years ago.

Whereas, Benjamin Ward Richardson, himself a potent theorizer, writing twenty-four years ago, seems to complain that in this "purely mechanical day, nothing is allowed that is not experimentally illustrated." For my part, I say, thank God for the change, if it has really come! It sometimes seems as though the day of theories and systems in medicine were drawing to its close, and that the dawn of scientific medicine were even now breaking. However, no teaching of the healing art can ever be called truly scientific that is not founded on the study of preventive medicine. The cure of disease is important, its prevention inconceiveably more so. We still have the cart before the horse, because we are still expending at least nineteen-twentieths of our energy and our resources in in studying curative medicine, and less than

one-twentieth in studying preventive medicine.

Brown's teachings were said to have led to the death of more human beings than all the wars of Napoleon and the French Revolution. We should not, however, blame any one man for the fashions in medicine; they are like the waves of the sea sweeping up and receding, often without specially obvious causes. Minute analysis of any particular theory yields the conviction that novelty has been perhaps more than any other attribute a determining factor in its popularity, and frequently the final adoption of the new theory has been in direct proportion to the vigor of the opposition with which its introduction has been assailed.

It is also to be observed that when in the history of medicine some particular therapeutic measure has been largely overdone the common sense of the plain people has finally overthrown it. In Brown's time the practices of bleeding and polypharmacy had been pushed to a shameful extent. Louis the XIV of France was bled 47 times in one year and took 215 different medicines and 212 enemata.

Dr. Quine informs us that in the latter part of the eighteenth century doctors were fined and imprisoned for having allowed any patient to die without having bled him. Boussat was banished from Paris, not because he failed to bleed a patient, nor because he had ever questioned the universal applicability of the lancet, but because he had the audacity to propose a new method of bleeding. Is it any wonder that public opinion at last revolted against the universality of this treatment and that physicians were forced to largely discontinue and finally abandon the practice of phlebotomy?

Radical changes in medical theory and practice, as said above, come in waves, and when once started sweep everything before them. The doctrines of Hahnemann, which were promulgated about the same time as Brown's, also, as you know, were strongly opposed to bloodletting. The time was ripe for this reform, and the leaders in it were really expressing public opinion, quite as much as forming new medical doctrines. Futhermore, Brown and Hahnemann lived in the age of new doctrines in medicine. The medical world had finally shaken itself free from the teachings of Galen, which had held undisputed sway for 1,500 years, and, since there was at that time no scientific basis for medical practice, systems must be invented to guide the floundering medical intellect into some sort of a harbor and pile up precedent and precept to prevent complete anarchy and disorder in the ranks of the physicians, as well as to guide the public into the belief that doctors had a solid reason for their beliefs and their practice.

Theories and systems afford a refuge for the unlearned and narrow medical mind. When it has mastered certain glittering generalities, which are true at least in so far that few can successfully dispute their truth, a feeling of satisfaction is engendered, because the rudiments of medical practice are thought to be secure. We have frequently seen as much anger and perturbation caused by any question of the absolute truth of an accepted doctrine in medicine as was caused among the ecclesiastical authorities by the teachings of Galileo.

We still have doctrines and systems and hypothetical explanations of natural phenomena, but the white light of science has grown too strong for us. The medicine of the future will, we believe, not be, like that of the past, largely controlled by dogma, superstition, and tradition. It will be scientific medicine and the true physician of the future will not be ashamed to say that he does not know a thing that science has not yet made clear to him, and will not condemn an innovation simply because it does not conform to his theories, and because he cannot measure it with his yardstick.

Fiat medicine like fiat money can make a great show. It can fool the laity and even arouse the wild enthusiasm of the prejudiced and unthinking practitioner. But it is not real medicine. There is no royal road to complete knowledge of our art or to the acquisition of skill in its practice. Only the student, the thinker, the man who is honest with himself, an unprejudiced observer, a merciless sceptic of pretense and assumption, and one who is capable of a lifetime of hard work can expect to be a real master of medicine.

THE USE OF ALCOHOL AND THE LIFE INSURANCE RISK.

By T. F. McMAHON, M.D.,

TORONTO, ONT.

ASSISTANT MEDICAL REFEREE THE MANUFACTURERS' LIFE ASSURANCE COMPANY.

THERE is no subject with which the medical referee has to deal that involves so much trouble and uncertainty as that connected with the drinking habits of the applicant. For many reasons it is impossible to get the truth even from applicants whose statements can be received with confidence in all other respects.

It is not my purpose to contend that the strictly moderate user of alcoholic beverages is to any appreciable extent a less desirable risk than a total abstainer. A man may drink a glass or two of wine or beer a day without rendering him a less desirable risk than a total abstainer. But we cannot deny that an abstainer is less likely to become later an immoderate user than one who habitually uses alcoholic drinks in moderation. He is less exposed to the temptations of the club, the barroom, and the sideboard, and there is less danger of him contracting vicious habits. We know how difficult it is to draw the line between moderation and excess. We are all familiar with the man who prides himself on his moderation, and would be much hurt at the suggestion that his daily consumption exceeds the limits of safety, and yet is in the habit of taking half a dozen or more drinks a day. He does not like to be questioned as to the exact number of drinks he takes, and if the examiner is conscientious and tries to get accurate information it is resented, and the applicant is apt to carry the business to another company. Bitter complaints follow from the agent and the examiner is likely to be supplanted by some one less likely to give offense. The applicant is usually unknown to the examiner, and even the ablest examiner cannot always distinguish moderate from immoderate drinkers. Thus it comes about that every company carries risks in large numbers on men who habitually or occasionally drink to excess.

We mentally classify risks according to drinking habits something after this scheme: (*a*) Total abstainers. (*b*) Strictly moderate drinkers. (*c*) Those claiming or believing themselves to be moderate drinkers, who, nevertheless, use alcohol in such amounts as to render themselves less desirable as risks than classes (*a*) and (*b*). (*d*) Immoderate drinkers.

In my opinion the only safe way to deal with immoderate drinkers is to reject them. If we attempt

to meet the danger by giving short term endowments and imposing liens, our experience will not be satisfactory for the reason that as a rule only the bad ones will accept such policies while the less undesirable will refuse to accept them. No matter what care we take, a large number who properly are graded in class (*c*) will get on our books. We can hope to keep down the number only by maintaining a high standard in our agents and medical examiners and by securing reports on habits from reliable and disinterested sources. But if there is to be any classification of the assured along this line, the only practicable one is into abstainers and non-abstainers. If the life expectancy of the average abstainer is higher than that of the average drinker who does not drink in such amounts as to make him uninsurable, it is surely only just that abstainers should be separately classified so that they may enjoy a lower rate on non-participating policies and share in the greater profits accruing upon the lives of the abstainers in the participating class.

THE USE OF ALCOHOL AND THE LIFE INSURANCE RISK.

In the year 1840 a certain Robert Warner—a members of the Society of Friends and a total abstainer—applied for a policy on his life. The directors of the company to which he applied would grant him a policy only on the condition that he paid 10 per cent. more than the ordinary premium, because they looked upon him "as thin and watery and as mentally cranked in that he repudiated the good creatures of God as found in alcoholic drinks." He refused to accept the policy thus loaded, and he and his friends banded themselves together and founded what is now known as the United Kingdom Temperance and General Provident Institution. Warner took the first policy and died at the ripe age of eighty-two years. This was the first company formed to insure the lives of total abstainers. The business at first restricted to abstainers was in 1848 extended to non-abstainers in a separate section. The above table shows their mortality experience under ordinary whole life policies for the forty-five years, 1866 to 1910, in 5-year periods.

The following are the percentages of actual to expected losses both as to number and amount:

Years.	Section and Percentage of Number		Section and Percentage of Amount	
	Temperance.	General.	Temperance.	General.
1866–70	74.86	93.65	72.35	117.28
1871–75	70.68	102.60	69.9	99.07
1876–80	69.77	99.73	65.10	103.63
1881–85	70.82	91.61	62.62	89.07
1886–90	68.95	94.79	72.08	90.64
1891–95	71.35	99.74	64.81	96.98
1896–00	73.79	90.52	73.29	89.07
1901–05	72.04	88.29	65.92	85.26
1906–10	65.21	83.26	59.75	79.91
Average	70.47	93.14	66.25	91.27

It will thus be seen that during the forty-five years from 1866 to 1910, inclusive, the number of expected claims from deaths was 12,754 in the temperance section and 15,794 in the general section, while the actual number of deaths was 8,988 in the temperance section and 14,711 in the general section. In other words, the percentage of actual to expected deaths in the temperance section was 70.47, while in the general section it was 93.14. The ratio of actual to expected losses as to amount was 66.25 per cent. in the temperance section and 91.27 per cent. in the general section. The mortality saving in the temperance section was therefore 3,766 lives during the forty years. In the general section with larger business it was only 1,083 lives. If the loss ratio had been as high in the temperance section as it was in the general section the mortality saving would have been only 875 lives instead of 3,766 lives. If the loss ratio in the general section had been as low as in the temperance section the mortality saving would have been 4,664 lives instead of only 1,083 lives.

The total saving from death losses being lower than the mortality tables called for was 4,849 lives in the two sections. With the same loss rate in both sections that was experienced in the general section, the mortality saving would have been only 1,958 lives. On the other hand it would have been 8,615 lives if the loss rate had been the same in both sections that it was in the temperance section. The ratio of mortality saving was on the average of 4.3 times as great in the temperance section as in the general section. In the forty-five years with a mortality in the whole business such as was experienced in the general section the total savings would have been only $3,045,495, but with a mortality in the whole business such as was experienced in the temperance section the savings would have been $11,775,465. The total actual mortality saving in the whole business was $7,070,658. The shortage in the general section on account of its less favorable mortality was $11,775,465 — $7,070,658 = $4,704,807.

MORTALITY EXPERIENCE UNDER ORDINARY WHOLE LIFE POLICIES, 1866–1910, 45 YEARS IN 5-YEAR PERIODS.

Total	129,540	1,451.9	629	43.3

Birmingham, Eng., published the preceding table compiled by its actuary with its annual report for 1910. It covers the period of twenty-seven years (1884-1910).

The Sceptre Life Association published the following table with its latest annual report:

Period.	GENERAL SECTION.			ABSTAINERS' SECTION		
	Expected Deaths	Actual Deaths	Per Cent.	Expected Deaths	Actual Deaths	Per Cent.
5 yrs., 1884-1888..	466	368	79.00	195	110	56.41
5 yrs., 1889-1893..	564	466	82.62	312	184	58.97
5 yrs., 1894-1898..	628	498	79.30	419	228	54.42
5 yrs., 1899-1903..	712	548	76.97	514	270	52.53
5 yrs., 1904-1908..	709	573	80.82	607	294	48.43
2 yrs., 1909-1910..	273	221	80.95	264	128	48.48
Total, 27 yrs...	3,352	2,674	79.77	2,311	1,214	52.53

The latest published experience of the Scottish Temperance Life, covering the period of twenty-five years (1883-1907), is as follows:

Period.	ABSTAINERS' SECTION			GENERAL SECTION.		
	Expected Claims	Actual Claims	Ratio, Per Cent.	Expected Claims	Actual Claims	Ratio, Per Cent.
1883 to 1887.....	43	15	35	11	7	62
1888 to 1892.....	159	79	50	49	33	68
1893 to 1897.....	290	138	48	95	67	70
1898 to 1902.....	444	188	42	164	118	72
1903 to 1907.....	609	298	49	223	123	55
	1,545	718	46	542	348	64

An interesting result is obtained by combining the figures of the Sceptre Life and the Scottish Temperance for a twenty-five-year period. It shows that during that period the two companies had a loss expectation of 3,621 lives in their general section and 3,592 in their abstainers' section, with actual losses of 2,801 in their general sections and 1,804 in their abstainers' sections. That is, they expected 29 more losses in their general sections than in their abstainers', and had actually 997 more losses.

In the ten-year period, from September 30, 1900, to September 30, 1910, the mortality experience of the Australasian Temperance & General Life Insurance Society was as follows:

	Expected Claims.	Actual Claims.	Percentage of Actual to Expected.	General Percentage of Abstainers.
Temperance section.....	$591,569	$278,497	47.1	.....
General section.....	303,322	229,572	75.7	160.7

In the first five years of the ten-year period under consideration the percentages of actual to expected losses were 50.1 in the abstainers' section, and 81.4 in the general section, while in the last five years the percentages were 44.8 and 70.8 respectively.

The Manufacturers Life, with which I am connected officially, has shown a remarkably low death rate among total abstainers. The experience of the Manufacturers Life in its Canadian business for the last nine years, 1902 to 1910 inclusive, is shown in the following table.

This experience is that of the last nine of the first twenty-five years of the company's business. It was even more favorable to total abstainers in the earlier years.

What is more significant than anything else is

Year.	PERCENTAGE OF EXPECTED MORTALITY.		
	Abstainers' Section.	General Section.	General Section Percentage of Abstainers' Section.
1902.....	36.9	67.5	184.4
1903.....	37.4	71.1	190.2
1904.....	42.5	61.9	145.7
1905.....	37.3	78.1	200.8
1906.....	35.9	56.6	160.0
1907.....	39.0	72.7	186.4
1908.....	38.2	82.1	214.9
1909.....	34.6	51.1	147.5
1910.....	30.3	50.7	167.4

Abstainers' average..... 36.90 per cent.
General average..... 65.75 per cent.
General percentage of abstainers..... 178.89 per cent.

the fact that a critical examination of the experience of every company separately classifying its risks reveals the fact that in every year and at all ages, wherever a considerable number of lives are under observation, mortality is much lower among abstainers than it is among non-abstainers. This is being recognized more and more by the British companies, several of which, while they do not maintain abstainers' sections, guarantee a permanently lower rate of premium.

116 St. George Street.

THE TREATMENT OF DIARRHEAS IN BOTTLE-FED INFANTS.*

By ROGER H. DENNETT, M.D.,

NEW YORK.

ASSISTANT ATTENDING PHYSICIAN, BABIES' WARDS, NEW YORK POST-GRADUATE HOSPITAL; INSTRUCTOR IN PEDIATRICS IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

The purpose of this paper is to discuss the results of my summer's work in diarrheas in bottle-fed infants. I have long been dissatisfied with the routine treatment of giving to every baby with a diarrhea a cathartic followed by a longer or shorter period of starvation. This work was based upon the single contention of Finklestein that sugar is the chief cause of diarrheas in artificially-fed infants. In this country we have looked upon the vast majority of these diarrheas as a bacterial invasion of the intestinal tract, so that the theory that sugars are the cause of even a part of such disturbances deserves investigation. Until the last year or so we have not thought much about the sugar in artificial feeding. It has been the custom in diarrheas, after a routine cathartic and period of starvation, to habitually start feeding various dilutions of top-milk, wheys, and cream mixtures, or what not, but quite universally 6 to 7 per cent. of sugar was given in the food at once. In order to come to some conclusion on the subject I adopted the routine method of cutting out all sugar in every case of diarrhea in my patients in private practice, and in the dispensary, and in the babies' wards. I had been feeding as a routine simply milk, water, and sugar mixtures. In these cases at the onset of a diarrhea I stopped the sugar, without changing the food in any other way except to boil the milk. The babies who had a diarrhea when they came to me, and who had been fed upon top-milk, or cream and whey mixtures and gruels or other foods, I put upon the routine mixture of one-third whole milk, and two-thirds water, without sugar. In the vast majority of cases this treatment was successful in controlling the diarrhea.

*Read before the Medical Association of the Greater City of New York October 16, 1911.

Many of these diarrheas occurred in the worst types of babies, those with extreme malnutrition and atrophy, or those that had had a diarrhea lasting weeks or even months, and those that had been upon a starvation diet for a prolonged period, with no improvement. These are three of the most resistant classes of cases, except, perhaps, those that are overwhelmed with an infection. The fact that some these diarrheas were not improved by this treatment impressed me more forcibly than ever with the lack of any satisfactory classification of diarrheas in infancy. For the want of a better method, and since this plan lent itself more easily to treatment, I have therefore classified them as follows: 1. Faulty feeding (indigestible mixtures); (2) insufficient feeding; (3) overfeeding; (4) infectious diarrhea.

Faulty Feeding: After being a top-milk and percentage feeding enthusiast for ten years I have finally come to the conclusion that babies with a weak digestion thrive far better on simple milk, water, and sugar mixtures and babies with a good digestion do just as well on these mixtures. I believe that top-milk mixtures especially in the hands of anyone but a skillful infant feeder are a very frequent source of diarrheas in the bottle fed. Gruels in very young infants are another cause. Young infants may stand a weak barley gruel, but often it is the cause of both gastric and intestinal indigestion. I have seen such babies stop vomiting and get normal stools by simply substituting water for the gruel without changing the food in any other way. I believe sugars are a still more important cause of diarrhea for the following reasons: (1) In the great majority of all my cases in hospital and private practice I have stopped diarrhea by omitting the sugar. (2) In other cases I have caused a diarrhea by giving too much sugar. (3) Constipation in bottle-fed babies can almost invariably be remedied by increasing the sugar when the child is fed on simple milk mixtures. (4) We also occasionally see intense intoxication by continuing sugar in sufficient quantity in a baby who already has a diarrhea from too much sugar. I believe milk sugar to be the least digestible. Cane sugar is usually well borne. Malt sugar (maltose and dextrine) is the best sugar of all, especially where there is a tendency toward diarrhea. The only preparation of malt sugar that I know of that is made in this country, is Dextri-Maltose. The leading German pediatricians have used this sugar for a long while, but the German preparation is very expensive when imported into this country. Other causes of diarrhea from incorrect feeding are irrational foods of any sort, such as condensed milk and some proprietary foods.

Babies who have a diarrhea from faulty feeding usually do not have any fever. The stools are numerous and may be watery or contain curds and mucus. There may or may not be vomiting. My last summer's experience has proven to me that such babies do not need a cathartic nor do they need starvation. With no preliminary treatment whatever they should at once be fed with whole milk and water boiled, with no artificial sugar added to the food. One-third milk and two-thirds water is a good routine mixture whatever the age, but with the older babies, half and half is well borne. This is given freely every two hours in the quantity which the well child of that age and weight should have. Vomiting is the only indication for reducing the quantity. In the vast majority of my cases the stools became more solid within one or two days. There was less mucus and there appeared in the stools light yellow masses which on cursory examination look like curds. They are, however, soft and homogeneous, and in my opinion are fecal masses showing the beginning of normal intestinal digestion. The next day these masses became larger and more numerous, making up the bulk of the stool, but might still be surrounded with some mucus. After the third or fourth day of a boiled milk and water diet the stools were usually pale yellow in color, sometimes pale green, and consisted of one large soft homogeneous mass with no mucus, which is a normal stool. They may be one, two or three in number. The number is not important. It is safer then to continue for a day or two more on this food, to which no sugar has been added, but the strength of the milk may be increased. When the sugar is added we should begin with small quantities. Say one-half ounce of sugar to the twenty-four hour amount of food, and gradually increase it up to one or one and one-half ounces. Rarely does the baby who has had a diarrhea stand more than that amount of sugar. If one and one-half ounces of sugar are given the first day it may bring about a return of the diarrhea. I have seen this done repeatedly. As in the following cases:

Case I.—I. T., 3 months of age. Weight 9 pounds, 12 ounces. Breast fed for a few days only; since then has been on top-milk mixtures. For the last month has had cream, top 5 ounces, water 14 ounces, sugar of milk 1 ounce, lime water 1 ounce. Vomits occasionally. Bowels loose, 6 or 7 stools a day, green watery with curds and much mucus. Seen August 4, and put upon milk 10 ounces, water 20 ounces, boiled, no sugar; 3 ounces every 2 hours and 10 feedings in twenty-four hours. August 8, four days later, the stools had become normal and the food was increased to 15 ounces milk and 20 ounces water (boiled) and 10 feedings of 3½ ounces each. Three days later, August 11, ½ ounce of maltose was added to this mixture with no return of the diarrhea. August 15, the food was increased to 18 ounces milk and 18 ounces water, and 1 ounce of maltose. On August 18, 1½ ounces of maltose were added to the mixture and since this gave him 122 calories per kilogram of body weight, he was getting sufficient food to make good gains thereafter.

Case II.—This is illustration of diarrhea caused by too much sugar. A. V., 4 months of age. Weight 11 pounds, 15 ounces. She had previously made continuous gains in weight on simple milk and water mixtures, to which 2 ounces of maltose had been added in each twenty-four hour feeding. On June 29, the food being 24 ounces milk and 16 ounces water, I added 2½ ounces of maltose to the twenty-four hour feeding, and two or three days later, diarrhea began with 5 or 6 loose, green, mucus stools a day. On July 6, without changing the food in any other way, I omitted the sugar, and on July 13, the stools were again normal. I then began with one ounce of maltose, and she did not have any further bowel disturbances throughout the summer.

The vast majority of cases went on to recovery with this method of feeding, but occasionally there were babies that did not do so. Such cases still continued to have a great deal of mucus in the stools, the mucus often being thoroughly mixed and intermingled with the rest of the stool without

any normal fecal masses appearing. After two or three days of such stools we know that our boiled milk and water treatment will not be successful. It is then necessary to start the *Eiweiss Milch* (casein milk) of Finkelstein. This is made in the following manner: One quart of milk is heated to 100 F. and two teaspoonfuls of rennet or essence of pepsin added. This is allowed to stand 15 to 20 minutes until jellied, then heated to 150 F., constantly stirring. The whey is then drained off through a wire colander and thrown away. Enough cold water is added to the curds to make a pint in all. The curds and water are then pressed through the wire sieve or colander with a wooden spoon two or three times until the curds become soft and fine. To this pint of curds and water one pint of real buttermilk (from the churn) is added. It should be used in the same amounts and at the same intervals as the boiled milk for a period of three to seven days, or until the stools are hard and dry. Then the boiled milk and water are substituted for it and the sugar is gradually added to the food as above described. This feeding will rarely fail us in stopping the most resistant diarrhea. Finkelstein's theory of its action is that the milk sugar being soluble in the whey which is discarded, the food is almost sugar-free. It would seem that there are other elements which must enter into reasons for its beneficial effect such as its coagulability in the gastrointestinal tract and the mechanical action of the casein or curds.

There was one particular class of babies that did much better on the *Eiweiss Milch* than they did on the boiled milk and water. These were the babies, who, during the summer had had many recurring attacks of diarrhea.

Insufficient Feeding: The best results that I got during the summer were in the underfed infants, so that this treatment seemed particularly applicable to this class of babies. Babies who have been wrongly fed are frequently put upon weaker and weaker foods until they are getting so little nourishment in the course of twenty-four hours, so few calories, that they not only cannot maintain their weight but they sometimes lose in weight and strength continuously. At the same time the stools do not improve, in fact they often go from bad to worse. In this same class of cases are the babies who have been given a barley gruel, weak condensed milk or some other starvation treatment, and kept upon it indefinitely. A cathartic only makes the bowel more irritable and aggravates the diarrhea. The boiled milk and water feeding as above described should at once be started. To those who have not used this method of feeding it appears wonderful to see the rapidity with which the stools become normal in this particular class of babies. I often see such babies who have had the diarrhea aggravated by the cathartic and their one chance of recovery lost by the inanition of lowered vitality which is directly caused by this period of starvation. How many cases do we see which go on from bad to worse and finally die under the old plan of treatment.

Case III.—J. W., 6 weeks of age. Weight at birth 7½ pounds. Present weight 6 pounds. 12 ounces. Never breast fed. Various foods until two weeks ago, when diarrhea began and has been fed barley gruel only since then, the diarrhea being unimproved. When seen on June 24, there were seven or eight stools a day, watery and brown in color, chiefly composed of thin mucus. The baby was restless and cried most of the time night and day. I prescribed a food composed of 8 ounces milk and 16 ounces water (boiled), feeding 2½ ounces of this mixture every two hours. Two days later, June 26, the stools were less numerous, three to four daily, containing a good deal of mucus with some normal fecal masses. June 28, the stools were three in number, still more solid and contained very little mucus. June 30, there were only two stools which were almost normal and the food was increased to 12 ounces of milk and 18 ounces of water (boiled), 3 ounces being given every two hours. After this the stools remained normal. On July 5, one-half ounce of sugar was added to this mixture and four days later the baby had gained 6 ounces in weight from water retention caused by adding the sugar. On July 9, 1 ounce of sugar was put into the twenty-four hour quantity of food, and a week later, on July 16, the sugar was increased to 1½ ounces. This gave the baby 127 calories of food per kilogram of weight and enabled him to make steady gains thereafter.

Occasionally these starvation cases go on to complete prostration. They have lost so much fluid from the body that they will die if they do not retain some water in the tissues. The eyes are sunken, the extremities are cold, the temperature subnormal and the bowels are loose. If such a baby has been fed on a sugar free diet he must at once have sugar added to the boiled milk and water, in order to save him. One and one-half ounces of maltose and dextrine are temporarily added to the food which will cause water retention through osmosis and the baby is tided over a critical period. I have seen infants gain nearly a pound in weight in twenty-four hours from water retention.

Overfeeding: In my early work upon caloric feeding I have occasionally kept on increasing the strength of the food with increased gains in weight until I fed a given baby so much food in twenty-four hours, so many calories, that he finally got a diarrhea. This was repeated so many times with so many different babies that I am thoroughly convinced that overfeeding, too many actual calories, is a frequent cause of diarrhea. This diarrhea I often stopped in my own cases by simply omitting the sugar without changing the food in any other way. In fact, the mothers of some of my feeding cases, observing the success of this plan of treatment, adopted it of their own accord. It was a fairly common occurrence to have a mother tell me that the baby had had a diarrhea the week before but that she had stopped the sugar for a day or two until the bowels became normal again. Cutting out the sugar of course, reduces the food value (the number of calories) a great deal as one ounce of sugar is equivalent to six ounces of milk. I believe that without keeping track of the number of calories per kilo or pound we are feeding a baby, we are in constant danger of overfeeding him and causing a diarrhea. It is such a simple matter to reckon calories when we know that every ounce of whole milk given in twenty-four hours equals twenty calories and every ounce of sugar equals one hundred and twenty calories. The average baby will do well on 120 calories per kilo. Atrophic, emaciated babies need as high as one hundred and fifty to one hundred and sixty calories per kilo. In these diarrheas from overfeeding the starvation does not do as much harm. In fact, I am not sure but that it is the best treatment in the older well-nourished babies. The gastrointestinal

tract needs a rest and the child can afford to lose weight for a few days. At the same time, I found that the boiled milk and water was not successful in as large a percentage of the older well-nourished babies. In some of my older babies, I persisted in this milk and water treatment for ten days to two weeks without getting good stools, only to find that twenty-four to forty-eight hours of a barley gruel diet, with no cathartic preceding it, brought about normal stools with ease. This may have been due to changing the intestinal flora according to the theory recently advanced. At any rate, I concluded that as a routine the barley gruel diet was more serviceable than the boiled milk and water in older babies who were well nourished or overfed. In the particularly resistant cases changing back and forth from one diet to the other every two or three days gave very good results.

Infectious Diarrhea: The signs of this condition are sudden onset of the diarrhea with fever usually accompanied by vomiting often with blood and mucus in the stools. Personally I saw through the summer comparatively few of these milk poisoning cases among a large number of the other varieties, and I believe that is due to the good milk supply in New York City. The treatment of these cases consists of the administration of a cathartic, if the case be seen early, and starvation for twenty-four to forty-eight hours. A weak barley gruel or boiled water may be used during this period. At the end of forty-eight hours at the most, whether the stools are better or not, I give boiled milk and water mixtures, or the *Eiweiss Milch*.

I have said nothing about drugs for the reason that I do not often use them. However, strychnine in doses of gr. 1/300 to 1/200 of a grain is very useful for the baby whose strength and resistance is poor or whose appetite is not good. Paregoric is occasionally useful in stopping vomiting which has become chronic.

I have not referred to those diarrheas caused by eating indigestible solid foods, because it is perfectly obvious that a cathartic is indicated, in cases in which such undigested substances remain within the intestinal tract. Nor do I include in this paper diarrheas in babies over a year of age which undoubtedly do best on a strictly carbohydrate diet.

In conclusion I will state that from a theoretical standpoint I do not feel sure that the mere absence of artificial sugar in the food is the cause of the beneficial effect upon the diarrhea. Boiling the milk changes it in many ways but I believe it makes the food more digestible. During the summer I did not see a single hard curd in any of the stools of my babies who were on boiled milk. At first I boiled my milk because Finkelstein and other German pediatrists do so as a routine and because it seemed desirable to follow them entirely. I continued to boil it in my diarrhea cases throughout the summer because I got such good results. I found, however, that boiling the milk has little or no effect upon the diarrhea when artificial sugar is added to the food.

From a practical standpoint, I came to the following conclusions: (1) Underfed, poorly nourished babies with diarrhea, do best on the milk and water mixture, boiled, without sugar. (2) Bad diarrheas, or those that do not improve upon these mixtures are benefited by *Eiweiss Milch*. (3) Babies that have had repeated or prolonged attacks of diarrheas do best upon *Eiweiss Milch*. (4) Older, well nourished babies with a diarrhea do best upon a barley gruel diet for a few days. (5) Infectious diarrheas, if seen early, should have a cathartic and starvation for forty-eight hours and no longer. The milk and water mixtures, boiled, or *Eiweiss Milch* should then be given. (6) Cathartics should be given to babies with diarrhea, with great discretion.

121 East Thirty-Eighth Street.

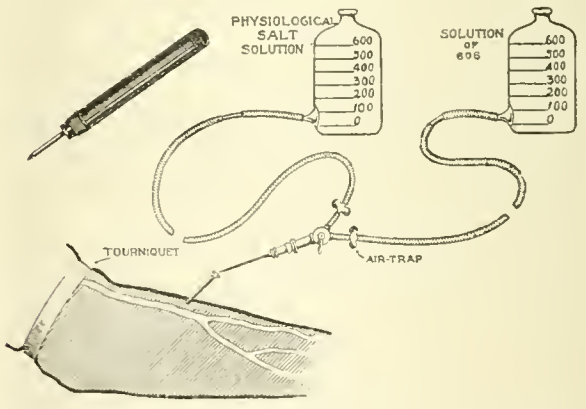
A BRIEF REPORT ON 414 INJECTIONS OF SALVARSAN.*

By EDGAR G. BALLENGER, M.D.,
AND
OMAR F. ELDER, M.D.,
ATLANTA, GA.

Since the first of January of this year we have administered 606 to nearly all of our syphilitic patients, and although the time is still too short to draw conclusions as to the absolute permanency of the cure, it seems quite certain that in 606 we have the best treatment for this disease. Never before have we had such a healthy, well nourished group of syphilitics, free from visible evidences of the disease, and with a feeling of well being rarely observed in those patients who have received the mercurial treatment.

The brevity of the paper will not permit a discussion of the details of this subject. Two things, however, seem to me to be of great importance: (1) The repetition of the treatment; (2) the method of administering the remedy.

The knowledge of the minute pathology of syphilitic lesions is of great importance in enabling



us to effect a permanent cure, as we may then understand the complicated conditions possible and see the necessity of subsequent injections regardless of the clinical cure or a negative Wassermann reaction. Competent observers believe that syphilis is not a blood disease in the sense that sleeping sickness is with the organisms living in the blood in infinite numbers. The treponema pallidum is thought to pass through the blood in large numbers only once (Wechselmann, Loewenthal, and Cannon) as search for them in the blood has furnished almost uniformly negative results. After having traversed the blood stream the spirochetes settle in the tissues in scattered foci. At these points lesions or recurrences develop. Ehrmann has clearly shown by injection preparations that spirochetes may become incapsulated in small blood vessels or lymph vessels, or connective tissue spaces by the cell growth thrown out by nature in her efforts to limit the spirochetal invasion. It

*Read before the Second District Medical Association, Dawson, Ga., September 20, 1911.

is to destroy the organisms thus protected that two or more injections seem necessary and, at times, previous or subsequent mercurial treatment. Since salvarsan is admitted to be much more destructive to the spirochetes than is mercury fewer foci of infection will probably remain after a series of treatments with 606. From the published reports and from our personal experience it seems that perhaps a good number of the patients who have received two injections of 606 are permanently well. This, however, we cannot know yet, nor until the time test has proved it, but as a course of mercury and iodide of potassium is not without deleterious influence upon the gastrointestinal tract and the patient's general health, it should not be recommended except where it seems clearly necessary to render permanent the good produced by 606. It does not seem expedient that we should subject all patients to mercurial treatment who have received several injections of 606, and are free from visible and subjective evidences of the disease, but rather those who remain uncured, who have recurrences, or who retain a positive Wassermann reaction. Several years of observation should be required before declaring that the disease is cured. The Wassermann reaction should not be relied upon implicitly when negative, but should be considered always in connection with the symptoms and clinical history, and disregarded when not in accord with them. When mercury is indicated it seems that the salicylate, in 10 per cent. suspension in liquid albolene, given intramuscularly in ¾ to 1 grain doses once weekly, is the most effective and satisfactory method of administering it.

Ten per cent. each of camphor and creosote previously mixed and added to the liquid albolene suspension lessens the pain which follows the injection and renders the preparation aseptic. A needle one inch long and about 18 or 20 gauge is used. Ten minimims of the suspension are drawn into the syringe, the needle is quickly inserted into the gluteal muscles and the pistons withdrawn so as to determine if a blood-vessel has been entered; if no blood appears in the barrel of the syringe the remedy is injected. The site is massaged for a moment and the puncture is then sealed with collodion.

Technique of Intravenous Injections.—The majority of investigators now believe that the best method of administering salvarsan is by the intravenous method; that this view is correct we are confident and have discontinued all other methods of giving it. Those who have administered many intravenous injections have at times experienced difficulty in inserting the needle directly into the vein, without a previous incision. As many patients were complaining of the telltale scars that remained, we endeavored to devise a method whereby all patients might receive the intravenous injection without the incision and herewith submit a simple plan which, in our hands, has greatly facilitated the insertion of the needle. A tourniquet is adjusted around the arm so as to make the veins stand out prominently. The largest one near the elbow is selected and a few drops of cocaine are injected into the skin over the vein and into the subcutaneous tissue around it. A point just over the vein is noted and, while the skin is pulled aside so as not to puncture the vein, a small trocar is inserted through the skin so that the distal end of the cannula lies just between the skin and the vein. With the cannula now held over the vein and at an angle of 30 degrees to it, the needle may be easily inserted into the vein. If further efforts are necessary in passing the needle very little inconvenience is experienced by the patient. The pressure required to carry the needle through the skin without the cannula in place tends to press the vein to one side or to flatten it out so that the needle passes through both walls of the vein. The cannula enables one to gauge more accurately the insertion of the needle. The escape of the blood from the punctures of the vein, which is likely to cause a confusing hematoma, may be lessened by using a needle with a sharp round point instead of one with cutting edges. No effort should be made to test the inward flow until a free stream of blood passes out into the tube when the physiological salt solution is lowered (see cut). The tourniquet is now loosened, the solution is raised about three feet above the patient's arm, and if it flows freely into the vein without a subcutaneous swelling the cock may be so adjusted as to allow the flow of the 606 solution, which with the same elevation flows into the vein slowly by gravity. The only dressing necessary after such a treatment is a small bit of collodion over the punctured wound. Occasionally the individual may be so fat that a suitable vein cannot be found or the veins may be so small that an incision from the first seems necessary. It is advisable not to prolong unduly the trials by the puncture method until experience has been acquired, but to make a small incision rather than to annoy the patient by tedious, unsuccessful attempts. The method just described undoubtedly facilitates the insertion of the needle and will lessen the number of cases in which an incision is required to secure a proper flow. In fact, we have not found it necessary to make incision in more than one per cent. of our last 200 administrations. The site of the injection should be watched for swelling, as a subcutaneous leak may occur toward the end of the injection even when it starts perfectly. A burning pain is also felt by the patient if there is a leak. If any untoward symptoms should develop during an injection the treatment should be discontinued. So far in our experience no symptoms have occurred that prevented the patients taking the full amount of 606 indicated, nor have the after-effects of the treatment seemed serious. An effort has been made always to regulate the dose to suit the physical condition and weight of the patient.

By-Effects and Recurrences.—We have so far administered 414 injections of 606 to 240 patients with practically no untoward by-effects, except in one patient who became unconscious on the 5th day after an intravenous injection of .5 gram. This coma-like condition lasted for about 20 hours and then the patient gradually became normal. Just what the cause of this condition was we are unable to say, but coming on so early after an injection we feel convinced it was in some way produced by the 606. This freedom from trouble so far experienced was probably due to very careful physical examinations of all patients and a regulation of the dose to suit the condition and weight of each individual. We have also insisted that all patients drink freely of plain water and lithia water the day of the treatment and for two weeks afterwards in order to dilute well the salvarsan as it is eliminated and thus prevent irritation of the kidneys. Nausea, vomiting, chills and fever of a few degrees were present to some extent in many patients during the first 24 hours after the treatment, but did not assume a

serious nature nor were the patients annoyed very much by these temporary disturbances. Many times there was no effect at all. The patients have nearly all willingly returned for subsequent treatment and expressed a preference for 606 to mercury when the latter had been previously taken. The use of the intravenous injection followed by another in a month, then subsequent injections of the salicylate of mercury when occasionally required, and if necessary even other injections of 606 have probably prevented the nervous recurrences that have been observed by other writers, as we have seen none. Two patients gave well marked signs of a recurrence of the disease, but were promptly cured of the visible evidences by another injection. Two patients were not completely cured by two intravenous doses of 606 and required a few weeks of mercury to complete the work. One patient with very large flat papular syphilide was not cured after four intravenous injections of 606 nor was there much improvement obtained by previous and subsequent applications of mercury. We believe that by persisting with mercury, potassium iodide tonics, and 606 we shall ultimately effect a cure in spite of the stubborn character of the disease in this patient.

MENTAL STRESS A POSSIBLE ETIOLOGICAL FACTOR IN CERTAIN CASES OF PELLAGRA.

By JOHN W. PRESTON, M.D.,

ROANOKE, VA.

The onset, course, termination, and mortality of pellagra furnish a striking parallel to tuberculosis, and in relation to the exact causative agent we stand at this time on precisely the same ground in the former as in the latter previous to Koch's discovery of the now well-known acid-fast bacillus. That pellagra has suddenly become widespread and has a selective capacity for certain individuals, some of whom readily succumb while others make a winning fight, is a matter of greatest interest and importance.

Barring here the discussion of the unknown organism or poison, which must be the proximal cause, the above mentioned selective action of the disease for certain individuals living under exact conditions with others of the same family and community who do not develop it can only be explained by the lowered resistance or lack of immunity on the part of those affected. That this lack of resistance has to do with the nervous system mainly would seem to be indicated by the following facts: The insane are especially predisposed; in a certain proportion of cases there is a nervous heredity; alcoholics are frequently attacked and usually quickly succumb; there is a period of vague and varying nervous symptoms of uncertain duration preceding the digestive and cutaneous lesions, which latter indeed may never develop, as has been emphasized by Harris.* The salivation, vomiting, and diarrhea in the beginning are unmistakably of a nervous character, and the skin manifestations have much in common with those due to the disturbance of its nutrition through the nervous system, notably surgical injuries and herpes zoster; and finally the pathological findings are chiefly in the nervous system.

That the poverty-stricken whose supply of carbohydrates is drawn largely from the poorer grades of corn products rather than from the higher-priced cereals, and the vicissitudes of whose lives render them more vulnerable to almost all diseases, are more susceptible is not questioned. It is to the well-fed, of good habits, who consume little or no corn, and who to appearances would seem to offer good resisting power that attention is here directed; with especial reference to the possible effect of mental stress, or trauma, if one may so express it, producing in the nervous system a fertile soil suitable to the development of the disease. The following cases may serve to illustrate the point:

Case I.—Mrs. H., white, American, aged 49 years. Father a suicide by hanging; mother and one brother died from tuberculosis; a sister is still living suffering from this disease; one brother was killed while intoxicated, and another is a paranoiac; two brothers are living and well. She had for some years undergone severe domestic worries, finally separating from her husband. In April, 1910, she suffered from an attack simulating a mild influenza, soon after which an additional misfortune befell her which worried her greatly. When seen August 10 she showed the typical nervous digestive and cutaneous manifestations of pellagra, which ran the usual course of fluctuating symptoms, with steady sapping of her vitality resulting in her death from exhaustion in October. Her habits had always been good.

Case II.—Mrs. W., aged 30, in good financial circumstances, food abundant and only of the best; never ate corn bread; was a splendid physical specimen. Heredity good, except that her mother recently suffered from "nervous prostration"; health was always good until the early spring months of this year, when, following closely upon a severe domestic disappointment and suspense, which continued on into the summer, she grew nervous and depressed, suffered from peculiar and varying nervous sensations about the limbs, "just like one getting out of a hot bath"; "gets angry at the least little thing." Digestion is easily upset and she gets loose movements of the bowels if excited. She had lost considerable weight. In June the characteristic skin lesions made their appearance, beginning on the back of the hands and forearms and progressing symmetrically on both arms to near the insertion of the deltoid. Her forehead and chin assumed a dark, leathery appearance. As cool weather now approaches the latter symptoms are clearing up, but nervous symptoms persist.

Case III.—Mrs. C., white, aged 47 years, was seen in consultation with Dr. Watson. She had always lived well and eaten a good variety of food. Previous to the present trouble she was well and robust. In February of this year she was greatly distressed by the death of her son's wife and a subsequent sharp contention over the guardianship of a child, following which she grew nervous and developed, as she expressed it, "crazy, curious spells," of vertigo, etc. In June she showed the typical cutaneous manifestations of pellagra, beginning, as she thought, as a sunburn and spreading symmetrically to the elbows. The forehead and chin likewise showed a well-marked bronzing. Under tonics, rest, and a liberal diet the symptoms are at this time subsiding, except the burning, tingling, etc., of the extremities.

While one recognizes that from the nature of this disease its victims fret and worry unduly over trifles, still when it follows closely upon misfor-

*Harris: *American Journal of the Medical Sciences*, 1911, xcii, 715.

tunes of sufficient magnitude to in a measure upset the nervous system of any normal individual as in the above cases, it would seem to make this phase of the question well worthy of consideration and further observation. Every one who has had to do with tuberculosis knows the futility of treatment so long as a patient is suffering greatly from anxiety, grief, or even homesickness, and how well one is often rewarded in the beginning of a case by efforts to ameliorate these and similar conditions. Since the two diseases have so much in common it may be that the lessons learned in the one may with advantage be utilized in the other.

309 South Jefferson Street.

HAMMOCK APPENDIX.*

By W. R. McKINLEY, M.D.,

COLUMBUS, MISS.

In using the title hammock appendix I do not mean to convey the idea that I have something new to report in appendix troubles. It is simply one of the many atypical conditions of appendix troubles I have encountered, usually in the chronic recurrent form in which this pathological condition occurs. In addition to the pathological condition with which we are all familiar, it obtains its significance or importance from its unusual situation, or, better expressed, predicament. Every surgeon will, of course, immediately conclude that my subject after all deals directly with abdominal adhesions. But while it is true that I am dealing with adhesions, it is the peculiar situation, attitude, or predicament in which the organ was found that suggested the appropriateness of the title. Every surgeon doing much abdominal work meets with appendix adhesions in great frequency. In fact they are to be looked for and expected in all pelvic inflammatory conditions.

The presence of adhesions and their resulting complications is a very great determining factor to operators in selecting their point of attack in abdominal and pelvic surgery. For instance it is the frequent occurrence of adhesions and their numerous complications that leads so many operators to select the abdominal instead of the vaginal route in many pelvic operations. In support of this we find that operations are frequently begun from below, but on account of complications encountered the route is abandoned and the operations finished from above.

Nearly all surgeons doing appendix work and who report their cases tell us how frequently they find the organ where they did not expect it to be before opening the abdomen, and it is these abnormally located appendices we find so difficult to resect.

A very frequent location in which we find the organ is on the posterior surface of the cecum, densely bound by adhesions, and, needless to say, the operation is extremely difficult in these cases. We sometimes find the appendix attached to the border of the spleen by bands of adhesions; we sometimes find it attached to the uterus, to the tubes, to the ovaries, or to the bladder, to the sigmoid flexure, or to the rectum; we sometimes find it attached to the intestines, to the anterior abdominal wall, and, as I have frequently seen, to the gall-bladder. Not only do we find the appendix at times bound by adhesions to all these organs, but sometimes it is a very difficult matter to find it at all; then again we find both the appendix and cecum bound down by an enormous mass of exudations and adhesions and covered by a sheet of newly formed connective tissue much like the peritoneum in appearance, thereby making its removal a very tedious undertaking. We find that our greatest aid is in careful inspection and in following the longitudinal bands marked on the anterior surface of the cecum.

Since we find the diseased organ in so many situations or positions we must expect to find a different array of symptoms from those found in a typical attack of appendicitis, since such organs as the gall-bladder, uterus, tubes, and ovaries add some of their symptoms to those of the primary disease. I have recently seen a case which an eminent internist referred to a surgeon with the diagnosis of distended gall-bladder, but the operation revealed one of those cases in which the diseased appendix was attached to the gall-bladder by adhesions.

In seven atypical cases under my observation the appendix was attached by adhesions to the right ovary, hanging, as it were, between the cecum and the ovary like an ordinary hammock, swinging like a swing between these two points. In these cases the appendix symptoms predominated, yet some of them were manifestly referable to the ovaries themselves.

In cases of this kind patients are necessarily subjected to many dangers, such as having loops of intestines wind round this hammock-like appendix, thereby causing obstruction, and are also liable to the danger of sudden perforation, the appendix being forced loose either from the ovary or the cecum—the point of disease, of course, being the point of least resistance. In one of my seven cases perforation had occurred before the belly was opened, and in two others perforations were noted in the distal end of the appendix when it was detached from the ovary.

McKinley Sanatorium.

*Read before the Southern Medical Association.

Treatment of Papilloma of the Larynx in the Young Child.—A. Broca and Ed. Rolando give us the results of their study of papillomata of the larynx in young children. This is a most intractable disease, since the growths rapidly occur after removal, and cause severe dyspnea and suffocation. Left alone this disease inevitably goes on to asphyxia due to obstruction of the larynx, since there is no tendency to spontaneous retrogression of the growth. Tracheotomy and intubation are but temporary palliative measures and only put off the time of fatal suffocation, since the child cannot go on indefinitely wearing a tube in his throat. Death may happen by reflex inhibition of the respiration. The voice becomes permanently rough or lost. The author concludes that there is no treatment that can be recommended as certain to preserve the voice, and to give probability of non-recurrence of the disease. Whenever there is alarming dyspnea the proper treatment is tracheotomy, hoping to produce enough atrophy of the growth to allow of operation by the natural passages. The procedure of choice is extraction in this manner under control of the head mirror, and this can be done after four years of age. It requires many sittings and recurrences are probable. When extraction by the natural passages is impossible on account of the extreme youth of the patient thyrotomy must be done. Definite success by this method is very rare. After these operations stenosis may make the removal of the tube impossible.—*Revue de Chirurgie.*

MEDICAL RECORD.

ANNUAL REPORT OF THE SURGEON-GENERAL OF THE UNITED STATES ARMY.

THE annual report of the Surgeon-General of the United States Army has recently been issued, and as usual contains a great deal of information of medical and public interest. The mean enlisted strength of the army, white and colored, for the year 1910, as reported on the monthly sick reports of the medical department was 71,534. This shows a considerable decrease in strength below that of 1909, for which the medical returns showed 74,319. During 1910 American troops were stationed in the United States, the Philippine Islands, Alaska, and Hawaii. The constantly non-effective rate which is the true measure of the loss in efficiency from sickness and injury was 35.98 per 1,000, as compared with 41.48 for 1909. The total admissions to sick report were 67,940, equal to an admission rate of 949.76, as compared with 1,062.99 for the previous year. The deaths from all causes numbered 320, of which 175 were from disease. The death rate from all causes was 4.46, and from disease it was 2.44, as compared with 4.91 and 3.02, respectively, for the preceding year. The death rate from disease is the lowest on record. The discharges for disability numbered 1,007, the rate being 14.02 as compared with 16.84 for 1909. The ratio of admission rates for disease for 1909 was 766.06 of mean strength; for the previous year it was 865.92. The mean strength of officers was 4,216 as obtained from the reports of the sick and wounded of the medical department. There were 2,515 admissions, 15 deaths, and 119.54 constantly non-effective from all causes, equal to ratios of 596.54, 3.40, and 28.35, as compared with the ratios of 628.90, 4.20, and 30.27 per 1,000 for 1909. The admission, constantly non-effective, and death rates were all lower than in 1909. The death rate from typhoid fever was less than in 1909, in fact, the lowest recorded in the service.

Perhaps the most instructive part of the entire report is that which refers to the success of anti-typhoid vaccination. During 1910, 16,093 persons were protected against typhoid fever by means of prophylactic vaccination. In only one case was the reaction deserving of special mention. A few cases of typhoid fever occurred among immunized men, but these cases were mild and all ended in recovery. It is worthy of note that compulsory vaccination against typhoid fever had never been attempted in any military service until used in our army in Texas and along the Mexican border in the spring of 1911.

The propaganda for the prevention of venereal diseases initiated by the army medical department in 1909 has begun to show good results. The admission rate for malaria for the army in the United States was the lowest on record. The admission and death rates for tuberculosis for the home army were less than for the two preceding years. The admission rate for alcoholism for the home army also showed a gratifying decrease. In this connection the Surgeon-General takes the opportunity to deplore the abolition of the canteen which, in his opinion, or rather as statistics seem to show has been, on the whole, coincident with the lamentable increase of alcoholism in the army.

With regard to sanitary matters some interesting information is given. It is stated that the Army Water Supply and Sewage Disposal Board, having made a study of ozone purification of water, recommended on February 11, 1911, the installation of an electric ozone plant at Fort Niagara. The hypochlorite method was not favorably considered at this post because it had failed to give satisfaction, chiefly because the water of the Niagara River is so heavily polluted. Moreover, it is announced that the board was also directed to consider a method of sterilization of water by the use of pure chlorine gas, which method had been devised and brought to the attention of the War Department by Major Carl R. Darnal of the medical corps. The board reported that the chlorine method is as efficient as purification by ozone or by hypochlorite, and is more reliable in operation. As to the health of the American troops in the Philippines, this continues to improve year by year. The admission rate was slightly higher than that of the army as a whole. In the Philippines venereal diseases still hold the first place, constituting more than one-fifth of the total number of admissions for disease. For alcoholism the admission rate was somewhat higher than in 1909. The total admission rate for all diseases among the white troops in the Philippines was lower than that for 1909. The most conspicuous feature of the nosological history of the Philippine scouts for the year 1910 is the eradication of beriberi, a disease which in the preceding year caused 41 per cent. of the total loss. The admissions and constantly non-effective rates were much lower for the Filipino than for American troops serving in the Philippines. Among Filipino troops venereal diseases constitute the second cause of admission, this good showing being entirely due to the fact that the majority of the native troops are married.

In the light of recent researches as to the cause of beriberi and the conclusions drawn therefrom the findings of the Tropical Board of the army in the Philippines should be of value. The board concluded that the important beriberi-preventing factor in the new Filipino ration, prescribed by

General Order No. 24, was neither mongo, nor camote, nor ginger root, nor undermilled rice *per se*, but was the substitution of part of the rice by mongo, but which might equally well have been another legume, such as beans, as recommended by the board on September 20, 1910. The question of beriberi and of some other diseases met with in the tropics is fully dealt with by the board. The report is satisfactory and speaks well for the ability and energy of the medical department of the United States Army.

ACTION OF THE TROPICAL SUN.

THERE are many who hold that white men succumb more or less quickly to the climate of the tropics, or if they do not die they deteriorate physically and mentally and that in short the inhabitant of the temperate zone is not physically adapted for a tropical life. These views would seem to have been borne out by experience, and yet there are some who contend that if the white man will only live with an eye open to the dangers of his surroundings and a care to shun them he may live in the tropics in fair health for the greater part of his life. In the *Philippine Journal of Science* appeared recently a paper by Hans Aron setting forth a series of experiments undertaken in the Physiological Laboratory of the College of Medicine and Surgery at Manila for the purpose of investigating the action of the tropical sun on men and animals.

The conclusions reached as a result of these investigations were interesting and valuable. These were as follows: (1) Under climatic conditions, even during the cooler seasons of the year in Manila, animals, such as rabbits and monkeys, which by nature have only a limited power of physical heat regulation, or animals the physical heat regulation of which is artificially inhibited, die if exposed to the sun, the body temperature rising to febrile heights. If the same animals are protected from the rays of the sun, or if the increase of heat due to radiation from the sun is compensated by an increased loss, such as would be brought by a strong wind, then the animals suffer no discomfort. Insolation of the skull alone is without effect if the body temperature is kept within normal limits. (2) The post-mortem examination of animals dying as a result of insolation shows decided hemorrhagic lesions of the brain and in monkeys of the heart. (3) In animals without sweat glands the subcutaneous tissues are heated by the radiated heat from the sun to temperatures above those compatible with life. (4) The human skin, if exposed to the sun, is warmed to about 3° or 4° above the normal skin temperature. An increase even to the normal body temperature is prevented by evaporation of sweat. The cooling effect of the sweat secretion causes a fall of the skin temperature even if insolation is continued during longer periods. (5) The brown skin of the Malays, while theoretically absorbing more heat in the sun, shows a smaller rise of temperature in the tropical sun than the skin of white men under similar conditions. As an explanation, it is believed that an earlier and greater evaporation by sweat secretion takes place. (6) The air in the human hair, especially in black hair, under the influence of the tropical sun, acquires a high temperature. (7) It is demonstrated that in the tropical sun a man with a colored skin is in a better position as regards heat regulation than is a man with a white skin.

It is pointed out that the monkey is a denizen of the woods and instinctively avoids the sun. The same is true of the native of the tropics, if he is left to his own customs. Consequently the argument is somewhat thus: A white man is not so well fitted by nature for tropical life as his colored brother. Outside the tropical diseases, for the most part carried by insects and avoidable by taking due precautions, the chief menace to the white man of a tropical climate is the sun. Therefore, in order to live in health in the tropics a white man should avoid exposure to the sun, especially in the interior, where the mitigating effects of the normal sea breeze are not experienced.

OCCUPATION HAZARDS.

THE New York State Factory Investigating Committee, created by the Legislature after the shirtwaist factory fire in Washington place, which cost 145 lives, has begun its deliberations; it expects by February next to make its report at Albany, and to prepare a bill for the remedy of existing defects and life-perils in factories. This committee will consider, of course, hazard to life because of fire, and such will perhaps be its main function; but it will inquire also into the following matters: accident prevention, the guarding of machinery, the proper and adequate inspection of factories and manufacturing establishments, the danger to life and health by reason of unsanitary conditions, ventilation, lighting, seating arrangement, hours of labor, and the like; such occupational diseases as "industrial consumption," lead poisoning, phosphorus necrosis, and so forth. It is with certain of these latter phases of industrial hazard that we are here concerned.

It is with gratifying emphasis that the counsel of this committee, Mr. A. I. Elkus, declares: "Occupational diseases, poisoning and industrial consumption, have practically been permitted to go on unchecked. Men are permitted to handle arsenic without gloves, to breath ammonia and turpentine fumes without protection, to fill their lungs all day long with dust and other harmful substances. Charity ineffectively palliates what wise and just special legislation might effectively prevent."

But are such things really permitted to go on unchecked to-day? Yes, they are. For example, a harmless process of manufacturing matches has been discovered, and the match company which owned this discovery generously divulged it to its competitors, nor would it protect itself by securing a patent in the premises. But since this discovery increases the manufacturing cost of matches by about 5 per cent., the new method has failed of general adoption. So the wasting of one match in twenty necessitates the continuance of "phossy jaw." Something of a remedy for this evil has been sought in the attempt to get a tax imposed on white phosphorus so high that its use in match making would be unprofitable, but the measure has thus

far failed of passage in Congress. Again, of two factories engaged in the production of white lead in one of the central States, one in which no effort was made to safeguard life, although employing only eighty hands, was compelled to renew virtually its entire working staff every ten weeks; the other establishment, conducted on principles more consistent with humanity and civilization, and employing twice as many hands, took on less than a hundred new workmen during the year.

The etiological relation between dusty trades and pulmonary disease has long been recognized. This relation is emphasized in a recent report issued by the Bureau of Labor at Washington, as follows:

CASES PER 100 WORKERS.

Class of Employment.	Tuberculosis.	Pneumonia
Workers in metallic dust.....	28	17.4
" " mineral dust.....	25.2	5.9
" " mixed dust.....	22.6	6
" " animal dust.....	20.8	7.7
" " vegetable dust.....	13.3	9.4
" " non-dusty trades.....	11.1	4.6

Still more strikingly is the tuberculosis mortality in the "dusty trades" shown by Mr. F. L. Hoffman.[1] We find that between the fifteenth and the sixty-fifth years the consumption deaths as against deaths from all causes in some of these trades are in the following percentages: Grinders, 49.2; plasterers, 38.7; brass workers, 38.9; instrument makers, engravers, 34.9; printers, 38.6; compositors, 35.1; stone-workers, 35.2; marble cutters, 28; glass cutters, 34.5; furriers and taxidermists, 32.4; silk mill workers, 35.9; bakers, 20.4; button makers, 37.8; leather workers, 32.0. But when we consider the life period between the twenty-fifth and the thirty-fourth years, we find the tuberculosis death rate truly appalling; as, among grinders, 70 per cent.; among engravers, 61 per cent.; compositors, 66 per cent.; stone-workers, 52 per cent.; millers, 87 per cent.; bakers, 42 per cent. And Mr. Hoffman observes that the contrast in the proportionate consumption mortality in indoor and outdoor occupations is truly startling.

To remove entirely occupation hazards is, of course, impossible; yet the dangers can be very greatly mitigated. And to this end it is proposed[2] that commissions be appointed by Congress to investigate these industrial evils; that medical clinics devoted exclusively to occupation diseases be established; that State governments employ medical inspectors of factories; that compulsory examinations of workingmen be made at definitely arranged periods; and that "employees' liability and compensation acts" be passed by legislatures.

[1] Tuberculosis as an Industrial Disease. Sixth International Congress on Tuberculosis, Vol. III, Section V, p. 141.

[2] Paul M. Peirce, Industrials Diseases, *North American Review*, October, 1911.

A PREMONITORY SIGN OF ACUTE INFECTIOUS DISEASES.

ANY addition to the diagnostic resources of the clinic is to be welcomed, particularly in the case of the acute infectious diseases of childhood, in which an early diagnosis is a prerequisite to efficient isolation and prophylaxis. As yet there has been no means of recognizing these individually or even as a group during the period of incubation. Giovanni da Gaetani Giunta, in the *Archiv für Kinderheilkunde*, Vol. 56, Nos. 4 to 6, reports that he has observed a symptom in some of the above diseases, even in earliest childhood, and at a period in the disease when there is no functional disturbance and before there are any demonstrable lesions. This premonitory sign consists in a swelling of the lymphatic glands of the axilla, neck, and groin, which is present during the incubation period of measles, scarlet fever, chicken-pox, mumps, diphtheria, and whooping-cough. The study of a large number of cases showed that in earliest childhood the lymphatic glands in the above-mentioned regions are ordinarily not palpable, but under the influence of various morbific agents they undergo the following changes: they are absolutely insensitive, both on spontaneous or passive movement; they present a variety of forms, in the majority of cases attaining the size of a lentil; they are most palpable and movable in the inguinal region. There is no marked correspondence between the axillary, cervical, and inguinal glands. The presence of this form of glandular enlargement may, according to the author, be regarded as a certain premonitory sign of an acute infectious disease. Neither age nor sex has any bearing on the occurrence of this symptom, nor does this vary with the variety of disease present. The presence of this sign depends upon neither inherited nor acquired predisposition. The sign does not indicate the severity of the infection or the degree of resistance in the patient.

The period of incubation of the infectious diseases has been termed by Royer the "silent period"; but, according to Giunta, this stage of the evolution of these diseases is one of marked activity, involving important functional and physical changes in the lymphatic glands. These act as a barrier to the invading microorganisms and their toxins. Not only do they serve as organs of inhibition and filtration, but they also elaborate the leucocytes and therefore play an important rôle in the fight of the entire body against the most diverse infections.

This function is a complicated one, is always being exercised, but with each new infection is aroused to increased activity. Moreover, the toxic substances produced in the various parenchymatous organs during the initial activity of the infecting agents cannot fail to affect the lymphatic apparatus. The latter is therefore the seat of numerous and profound changes in its inner workings, which as yet have escaped the searching eyes of science. The enlargement that accompanies these changes during the period of incubation of an infectious disease is not, however, a constant phenomenon. When present it may be the result of a lymphatic hyperfunction caused by functional changes in innervation; or of a more greatly developed reactive power of the glands with respect to toxic influences. There is a third possibility, namely, the glands may be the seat of a permanent latent microbic infection which predisposes them to added infection and hence to enlargement. This latter possibility, however, is not regarded by the author as of any moment in the production of his premonitory symptom of infectious disease.

THE HORSE AND THE AUTOMOBILE.

Dr. Walter Lindley of Los Angeles and twenty-four Californian physicians discuss in the *Southern California Practitioner* of October, 1911, the inferiority of the horse to the automobile from the hygienic point of view. At the recent California State Board examination Dr. Lindley asked, as one of the questions in hygiene: What are the hygienic advantages of the automobile over the horse at home and in the street? Naturally, from twenty-four medical men a large number of points of superiority of the automobile over the horse were given. Within the limits of an editorial article there is no space to note more than the general trend of these answers. Of course, the menace of horse manure was the feature chiefly dwelt on, and this menace, mainly in connection with manure as a breeding place for flies. Pollution of wells from stables was mentioned. The horse as the disseminator of the tetanus bacillus was referred to, also the danger of horses communicating glanders, the possibility of actinomycosis being communicated by the horse, etc. Several answers laid stress upon the fact that additional air and sunshine were enjoyed by those who had automobiles.

It would be interesting to learn from a company of medical men in what respects they might consider the horse superior to the automobile from the hygienic standpoint. No doubt the horse is a menace to health to a certain extent in a city, chiefly by reason of his stable affording a breeding place for flies. On the other hand, the automobile in a city has to answer for the promotion of more noise than was the case before its advent. This, too, affects the general population, perhaps, more than the motorist himself. Whether the automobile has increased nervous complaints to an appreciable degree is a moot point. There is, also, the question of dust dissemination to be considered when discussing the automobile. From the esthetic point of view there is room for comparison, but even from the hygienic standpoint solely the lover of the horse and the votary of the motor car would, doubtless, argue stoutly with regard to the relative merits of the animal and of the machine and each would give cogent reasons for his attitude. Apart from the question of hygiene, however, the superiority of the machine over the horse, so far as the physician is concerned, is so marked and so proved by experience that it is probable no consideration will ever bring back the animal to the service of medicine except as a provider of antitoxins.

News of the Week.

A Misstatement.—In the *New York Times* of Sunday last there was printed an article on the treatment of arteriosclerosis which purported to have been read by Dr. Bruno Fellner, Jr., of Franzenbad, at a meeting of the Medical Association of the Greater City of New York on November 20. The remedy for arteriosclerosis proposed by Dr. Fellner was a drug which once enjoyed a reputation as an aphrodisiac. The chief point of interest in the paper, however, was that it was not read before the Medical Association of the Greater City of New York, and as is stated in a resolution of the Council of the Society passed on Tuesday of this week the character of the paper was such that the Society would not have permitted it to be presented to its members.

Smallpox in Vermont.—Several hundred cases of smallpox are reported to have occurred in northern Vermont in the vicinity of St. Johnsbury and of Greensboro. Whether the cases are really of smallpox seems uncertain as it is stated that among the large number of persons attacked there have been no deaths.

Work of Pennsylvania's Health Department.—The Legislature of Pennsylvania last year appropriated $3,000,000 for its public health, $2,000,000 of which was to be expended in the fight against tuberculosis, and $1,000,000 to combat other diseases. During the past four years the number of deaths per annum has been decreased 14,000. It is estimated that about 2,500 deaths from typhoid fever and 7,000 from diphtheria were prevented last year by the activities of the State Health Department. The State maintains three sanatoria and 115 dispensaries for the treatment of tuberculosis and during the past year treated 40,000 cases of that disease. Taking the lowest estimated value of a human life, $1,700, it is calculated that the economic saving to the State through this reduction of the death rate amounts to $24,000,000 for the year. Preliminary arrangements have been made for the medical inspection of girls and boys in the third and fourth class school districts throughout the State. Five hundred physicians will be appointed to the task which embraces the examination of children in 321 boroughs and 460 townships.

The Board of Health on Watch for Infantile Paralysis.—The New York Department of Health has assigned inspectors to all orthopedic hospitals and dispensaries to insure the complete report of all cases of infantile paralysis. Circulars will be issued by the Board of Health and distributed to every family in which the disease occurs giving information regarding the disease and its treatment. The minimum quarantine will be six weeks, after which disinfection or house renovation will be made obligatory. Circulars calling attention to these requirements will be sent to all physicians and they will henceforth be required to report promptly to the Board of Health all cases which they are called on to treat.

Railroad Hospital to Be Opened.—The Western Pacific Railroad Hospital, located at Portola, is about ready for occupancy. It is the only hospital on the Western Pacific between Salt Lake City and Sacramento.

Gifts to Hospitals.—The will of John M. Lohse leaves $10,000 to the Presbyterian Hospital of New York City and $15,000 to the German Hospital. The latter institution has also received $10,000 under the will of Mrs. Elise Timme. The Dickinson Hospital at Holyoke, Mass., has received a bequest of $2,000. Before the Alaska-Yukon-Pacific Exposition the Anti-Tuberculosis League of Seattle received a donation of a large amount of the stock of this exposition, which upon a distribution of dividend recently has yielded the League $14.122. By the will of Mr. Frank Haseltine of Philadelphia, who died in 1910, the sum of $29,650 is bequeathed to the University, Jefferson, and Pennsylvania Hospitals. Under the terms of the will of Mrs. Sarah V. Feddyplace the hospital of Salem, Mass., received $2,000. The hospital at Brockton,

Mass., has received a gift of $500. A charity ball has just netted $2,500 for St. Mark's Hospital of Salt Lake City.

The Hospital Saturday and Sunday Association of New York City in its annual report recently made public states that the amount contributed to the association during the year was $116,000, or an increase of about 28 per cent. over 1910. The report says that $200,000 is badly needed to care for the dependent sick in the city. During the past year some 1,235,524 days of free hospital treatment were given by the 45 hospitals belonging to the Hospital Saturday and Sunday Association. The last Saturday and Sunday in the year are the days set apart by the churches for this collection.

The National Association for the Study and Prevention of Tuberculosis has received a donation of $50,000 worth of vacuum cleaners from a firm in New York City to be given as prizes for those who sell the most Red Cross Christmas seals. A stationary vacuum cleaning system will be given to the school in each of the thirteen Congressional districts which sells the most stamps. The State Charities Aid Association announces tweny-one different contests, one State contest for cities of 5,000 or over, and a contest for each of the Congressional districts in its territory. Through a special donation the association will give to schools as the prize for each district a full equipment of "The Control of Body and Mind" by Dr. Luther Halsey Gulick.

Minneapolis Opens a New Hospital.—The new Hopewell Hospital, a model institution for tuberculous patients, erected at a cost of $80,000, will be ready to receive patients on December 1.

Nursing-Bottle Fatalities.—According to the records of the State Board of Health of California the percentage of deaths in that State of infants under five months of age is 49. Most of these deaths were due to intestinal diseases for which the Board of Health holds the nursing-bottle responsible.

Physicians Regulate Fees.—The physicians of Norwalk, Ohio, have agreed to raise their charges to $1 as the minimum office fee and $2 for house calls between the hours of 9 A. M. and 6 P. M.

Standardization of Germicides.—The State Board of Health of Kansas has determined the standard for germicides and disinfectants in the State of Kansas. The ruling says "An article or substance which is designated as 'germicide' or 'disinfectant' will be held to be of such character when it will actually kill any nonspore-bearing bacterium within six hours under the conditions prescribed for its use."

Must Report Tuberculosis in England.—Under an order issued by the Local Government Board every practitioner in England must report cases of pulmonary tuberculosis after January 1. In a circular accompanying the order it was pointed out that the death rate from pulmonary tuberculosis was 18.25 per 10,000 of population in 1881, while it was 10.30 per 10,000 in 1900; this period coincided with the marked increase in the activities of the local authorities. It is urged that all publicity is to be avoided and that the reports are to be regarded as strictly confidential documents.

To Rent Medical and Surgical Appliances.—A large medical supply company is about to open a place in Chicago where all kinds of appliances which may be needed in surgery or in the sick room may be rented by those unable to buy them. For emergency cases attendants, nurses, ambulances, and chests will be kept in readiness at any hour of the day or night. A special food department, modeled after an establishment of the kind in New York, will also be maintained.

Many Adulterations of Food and Drugs.—During the past fiscal year the Bureau of Chemistry of the Department of Agriculture, Washington, D. C., collected 9,500 official samples of foods and drugs, of which 3,280 interstate samples were found to be legal, and 3,113 misbranded or adulterated; 503 check analyses were made to insure that correct results were obtained before recommending action on the samples. There were 96,129 floor inspections made of imported products, of which over one-half were made in New York. A total of 9,698 imported foods and drugs were analyzed, of which number 3,085 were adjudged adulterated or misbranded.

Suicides in American Cities.—According to the *Spectator* the combined suicide rate of 100 American cities, which was 21.8 per 100,000 population in 1908 and 21 in 1909, fell to -9.7 in 1910. The rate for the city of New York was 18.9. San Francisco has the highest suicide rate, the yearly average being 52 to 100,000 inhabitants for the period of 1900 to 1909, although in 1909 the rate fell to 42. Suicide has been most frequent during the last 10 years in five California cities and in Hoboken, N. J., which has a rate of 35 per 100,000 inhabitants, which is the third highest in the list of 100 cities.

The Campaign for the Prevention of Insanity.—The Committee on Mental Hygiene of the State Charities Aid Association has just reported on its first year's campaign of education on the prevention of insanity. During this year 360,000 persons have received a pamphlet entitled "Why should anyone go insane?" This gives some of the facts as to the extent, causes, and prevention of insanity, and is issued for lay circualtion. Another feature of the campaign has been the sending out of 24,845 circular letters to physicians, clergymen, teachers, social workers, and heads of various organizations asking their cooperation. It is estimated that by the various methods employed more than 500,000 persons have been reached by this new campaign. Among the new agencies for the treatment of incipient insanity inaugurated this year are the outpatient department of the Long Island State Hospital, Brooklyn, the new Psychopathic Hospital, Syracuse, and plans for two clinics for mental diseases, one of which is to be established at Kings County Hospital and the other at the new Gouverneur Dispensary, New York City.

Passed Assistant Surgeon George W. McCoy of the U. S. Public Health and Marine-Hospital Service has been relieved as Director of the Federal Plague Laboratory at San Francisco, Cal., and detailed Director of the U. S. Leprosy Investigation Station, Honolulu, Hawaii.

Dr. C. J. Wallace of Duluth has been appointed surgeon for the new steel plant built by the Minnesota Steel Company. The company is to build a large hospital in connection with the steel plant.

Dr. Hiram J. Smith of the Elgin State Hospital of Indiana has been appointed assistant superintendent of the Watertown State Hospital.

Dr. M. Karpas of the Manhattan State Hospital has been appointed first assistant in the psychopathic ward at Bellevue Hospital.

Dr. T. J. Vosburgh has been appointed first

assistant in the alcoholic ward at Bellevue Hospital.

Dr. Albert E. Ferris of New York City has resigned as president of the State Commission in Lunacy. He was appointed in 1907 by Governor Hughes. Dr. Max Schlapp of this city, it is reported, will be appointed to succeed Dr. Ferris.

Dr. J. M. T. Finney of Johns Hopkins University, Baltimore, has declined to allow his name to come before the trustees for nomination to the presidency of Princeton University.

Portrait of Dr. Wyeth.—It is proposed to purchase a portrait of Dr. John A. Wyeth for presentation to the Gallery of Presidents of the New York Academy of Medicine, by subscription of members.

Jewish Hospital Reports.—The annual report of this hospital shows that 4,124 persons have been treated during the year ended October 31, an increase of 15.5 per cent. over the previous year. In addition to the $1,000 which he gives annually to the hospital, Jacob Schiff has offered to give $500 for every $10,000 the hospital authorities might collect. An announcement was made of a donation of $2,500 to be devoted to the maintenance of an .r-ray room. The gifts for the year amounted to $7,466.

Jewish Consumptives' Hospital.—The annual meeting of the trustees of the National Jewish Hospital of Consumptives, which is located at Denver, was held at the Hotel Astor on November 19. It was announced that the $70,000 lost by defalcation by the secretary, who died in August, had been more than made up. The hospital now has accommodations for 150 patients. During the year a trade school has been donated in memory of Joseph E. Schoenberg, a former trustee, in which convalescents will be trained in labors suitable to their constitution so that they may have a healthful means of gaining a livelihood. A farm of 700 acres has also been given by Louis Schoenberg. It is said that 65 per cent. of the patients are Russians and about 40 per cent. of those admitted are from the congested districts of New York City.

French Birth Rate Declines.—The official statistics for the first six months of 1911 show that the excess of deaths over births is 18,279. During the same period of 1910 the births exceeded the deaths by 21,189.

Aid Association of the Philadelphia County Medical Society.—At the annual meeting held November 14 the following officers were elected for the ensuing year: *President*, Dr. Roland G. Curtin; *Vice-President*, Dr. Jacob R. Shellenberger; *Treasurer*, Dr. Lewis H. Adler, Jr. An appropriation of $200 was made for the physicians who were sufferers as a result of the flood at Austin, Pa.

The American Association for the Conservation of Vision is inaugurating a widespread campaign of public education to call the attention of people to the care and preservation of their eyesight. The association has recently moved to new offices at 105 East Twenty-second street, New York City. A recent election of officers leaves the personnel as follows: *President*, Dr. F. Park Lewis; *Vice-President*, E. L. Elliott; *Acting Secretary*, Douglas C. McMurtrie; *Acting Treasurer*, T. Commerford Martin. Dr. Hiram Woods of Baltimore is on the board of managers and Dr. G. E. de Schweinitz of Philadelphia is director of the Department of Diseases and Defects of the Eye. Among the publications of the association are its *Bulletin* and *Monograph Series*, the first of a popular and the latter of a technical nature. The first issue of the *Bulletin* is entitled "Conserving Vision," compiled by Douglas C. McMurtrie and edited by G. E. de Schweinitz, M.D., F. Park Lewis, M.D., Louis Bell, Ph.D., and E. Leavenworth Elliott. The first issue of the *Monograph Series*, edited by Douglas C. McMurtrie, is entitled "Ophthalmia Neonatorum in Ten Massachusetts Cities" by Henry Copley Greene. The association has now in press additional instructive booklets of a popular nature.

The American Guild of St. Luke.—The next meeting of this Society will be held on December 8, 1911, at 8.30 P. M., at the Catholic Club, 120 West Fifty-ninth street, New York City. Dr. James J. Walsh will read a memoir of the late Prof. Thomas Dwight, the Harvard anatomist, and a general discussion will be held on the subject: "When Is the Induction of Premature Labor Justifiable?" Non-members desiring to attend should communicate with the president of the society, Dr. Charles E. Nammack, 42 East Twenty-ninth street.

The American Public Health Association will hold its thirty-ninth annual meeting in Havana, Cuba, from December 5 to 9. The headquarters of the association will be at the Hotel Sevilla. Dr. William C. Woodward is the secretary.

The Pan-American Sanitary Conference held its fifth annual meeting at Santiago, Chile, on November 6, 7, and 8.

The Canadian Public Health Association will open its first annual meeting at McGill University, Montreal, on the evening of December 13, on which occasion His Royal Highness, the Duke of Connaught, will deliver the opening address.

The Homeopathic Medical Society of Delaware State and Peninsula, recently in session in Wilmington, elected the following officers: *President*, Dr. W. F. Hoey, Frederica; *Vice-President*, Dr. E. Q. Bullock, Wilmington; *Secretary*, Dr. Victor D. Washburn, Wilmington; *Treasurer*, Dr. H. W. Howell, Wilmington.

The Sixth International Congress of Obstetrics and Gynecology will be held in Berlin September 10, 11, and 12, 1912. The German Gynecological Society and that of Berlin will join with the Organization Committee in the reception of the International Congress in Berlin. The subject for discussion proposed is: "The Treatment of Peritoneal Wounds in Relation to Obstetrics and Gynecology." Some large national associations have already appointed their referee. During the session of the Congress an exhibition of obstetrical and gynecological specimens, objects for demonstration, instruments, and apparatus will take place.

The Southern Medical Association, which held its fifth annual session at Hattiesburg, Miss., on November 14, 15, and 16, elected the following officers: *President*, Dr. J. M. Jackson of Miami, Fla.; *Vice-Presidents*, Dr. Frank A. Jones of Memphis, Tenn., and Dr. D. J. Williams of Ellisville, Miss.; *Secretary-Treasurer*, Dr. Seale Harris of Mobile, Ala. Changes in the constitution and by-laws of the association were made whereby Texas, Arkansas, Kentucky, West Virginia, Maryland, North Carolina, South Carolina, and the District of Columbia were taken into the association.

The Tri-State Medical Society, Arkansas, Texas, and Louisiana, which convened in Little Rock, Ark., on November 14, elected the following officers: *President*, Dr. E. H. Martin of Hot Springs; *Vice-Presidents*, Drs. T. F. Kittrell of

Texarkana, J. F. Rosborough of Marshall, Texas, and Knighton of Shreveport, La.

The East Texas Medical Society, which met in Little Rock in joint session with the Tri-State Medical Society, elected the following officers: *President,* Dr. Samuel Ball of New Boston; *Vice-President,* Dr. E. Y. Anthony of Omaha; *Secretary,* Dr. H. T. Mann of Texarkana; *Treasurer,* Dr. C. A. Smith of Texarkana.

Obituary Notes.—Dr. Elmer Fletcher of Eugene, Ore., died suddenly November 10. He was 49 years old.

Dr. Joseph Waldauer of Vicksburg, Miss., a graduate of the Louisville Medical College in 1894, died at his home November 10.

Dr. James S. Daniel, a graduate of Chattanooga Medical College in 1893, died at his home in Danielsville, Ga., November 12, aged 42.

Dr. David R. Wallace of Waco, Texas., died at his home November 21 at the age of 87. He was a graduate of the Bellevue Hospital Medical College in 1854.

Dr. William D. Barclay, a graduate of the Hospital College of Medicine, Louisville, Ky., died at his home in Odessa, Mo., aged 42.

Dr. William J. H. Ballamy, a graduate of New York University Medical College in 1868, died at his home in Wilmington, N. C., November 18, aged 67.

Dr. James Frederick William Ross of Toronto died on November 17 at Richmond Hill, Ont., from injuries received in an automobile accident. He was born in 1857 and graduated from Trinity Medical College in 1870. He was professor of gynecology at the Toronto University.

Dr. H. C. Barkhausen died at his home in Unity, Ill., on November 8 at the age of 95 years.

Dr. B. Brindley Eads, surgeon at the Cook County Hospital and Dean of the Illinois Medical College, died at his home in Chicago, Ill., on November 10. He was born in Paris, Ky., January 23, 1870, was graduated from Jefferson Medical College, Philadelphia, in 1891, and began the practice of medicine in Chicago in 1892. He was at one time professor of physiology and anatomy in Rush Medical College.

Rear-Admiral John Yeatman Taylor, formerly a Medical Director of the United States Navy, took his own life because of ill health on November 16 at his home in Washington, D. C. He was born in East Nottingham, Pa., and was graduated from Jefferson Medical College in 1852. He was with Farragut on the *Oneida* in the battle of Mobile Bay, where re won distinction, in recognition of which he was advanced to the rank of Rear-Admiral in 1906. He was 82 years of age.

Dr. Eugene Wasdin, Surgeon U. S. Public Health and Marine-Hospital Service, died on November 17 at Gladwyn, Pa. He was born in 1869 and was graduated from the Medical College of the State of South Carolina in 1882. He entered the Marine-Hospital Service in 1883 and was commissioned surgeon in 1898. Dr. Wardin was in Buffalo at the time of the assassination of President McKinley, and was one of the surgeons in attendance upon him. He was at one time a member of the yellow fever commission of the Marine-Hospital Service, and wrote much upon the subject.

Dr. James B. Jones, retired, for sixteen years president of William Wood College at Fulton, Mo., died at Winston-Salem, N. C., on November 8, at the age of 65 years.

Correspondence.

IPECAC IN DYSENTERY AND TYPHOID FEVER.

To the Editor of the Medical Record:

Sir:—The Medical Record has recently published two articles which bring up old memories of my service in the "New York Hospital" (1867 and 1868) and suggest a question which I have never heard discussed, viz., How does ipecac effect the remarkable cures of dysentery which are vouched for by so many trustworthy authorities?

In 1867 the New York Hospital was, if I remember rightly, under contract to care for, in its wards, a fixed number of the employees of the Panama Railroad (or Steamship Company?), and so it came about that during that summer, for weeks at a time, the beds of one of the medical wards were occupied by patients affected with dysentery or with "Panama fever," a most virulent type of malarial infection, that resulted, in not a few instances, in death. When the first batch of dysentery patients were brought into the hospital the physician who was then in attendance (Dr. Charles E. Hackley, since deceased) instructed the house staff at first to use opium and vegetable astringents freely; but when it became evident, as it soon did, that this plan of treatment was not likely to cure the disease, he ordered the adoption of what was then known as the East Indian method of treating dysentery. As it was then—and doubtless still is—the practice for the house staff to keep a careful record of every case treated in the hospital, I have no doubt that anybody who is interested in the subject will find, in the volume of case records for 1867 (or 1868), a detailed account of the hospital's experience with the East Indian ipecac treatment of tropical dysentery.* There remain in my memory simply a few facts relating to the cases in which this mode of treatment was employed. The doses of powdered ipecac administered were relatively large—15 or 20 grains; they were given only once a day and were invariably preceded by the application of a strong mustard plaster over the region of the stomach; as the character of the stools improved, which they very soon did in nearly every instance, the dose was gradually diminished; and, finally, in the course of from four to six weeks, nearly every one of these patients was "discharged cured." These facts, if I have remembered them correctly, are in full harmony with those observed by medical practitioners in the Philippine Islands, as stated by Dr. Andresen of Brooklyn, and also with the latter's personal experience.

The marvelous action of this drug, ipecac, upon the intestinal parasites which are now known to be the causative factors of tropical dysentery suggests at once the question, What is the *modus operandi* of the remedy? Does it mingle with the contents of the intestinal canal and in this manner eventually reach and destroy the harmful parasites, or is it gradually absorbed by the gastrointestinal blood-vessels and thus, in all probability, more rapidly conveyed to every part of the body, the secreting structures of the intestinal mucous membrane included? The great efficiency of ipecac in

*The volumes referred to are probably still in the possession of the New York Hospital, in West Sixteenth Street, or possibly they may be in the custody of the Academy of Medicine, in West Forty-third Street.

alleviating bronchial inflammatory disorders in which bacterial organisms play an important part suggests the likelihood that the drug, or at least a large part of the dose administered, reaches the affected intestinal area in precisely the same manner as it does the inflamed bronchi, that is, by way of the circulating blood. And if it be true that, as here assumed, one of the chief effects of ipecac is to destroy certain bacteria which find their way into the human body, why is it not reasonable to believe, as Dr. Frazier of Mountain Home, Idaho, maintains, that the drug may be administered to advantage in typhoid fever?

ALBERT H. BUCK, M.D.

HEWLETT, LONG ISLAND, N. Y.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

THE INSURANCE BILL—ROYAL COLLEGE OF SURGEONS PRESIDENCY—GENERAL PARALYSIS OF THE INSANE—DR. COUTTS—OBITUARY—SIR S. WILKS AND MAJ.-GEN. MEADOWS.

LONDON, November 10, 1911.

THE insurance bill is being pushed through with a determination which some condemn as unscrupulous and others say is sheer obstinacy. Yesterday nine clauses were passed under the guillotine. There was, of course, a mere pretence of discussion, and that only on the proposal to empower approved societies and health committees to recover from defaulting local authorities or employers the cost of expenditure on excessive sickness. The chancellor held that it was desirable to make neglect unremunerative, and made statements which were regaded as unfair attacks on existing sanitary authorities. The title health committees being objected to, he half promised to substitute insurance committees. Whatever they may be called, it was urged they should be under existing health authorities. It was further held there is no need of them, and parliament ought not to multiply machinery which might overlap or interfere with that which is working well.

The most important question for the profession remains: Should we accept the contract system of practice or insist on payment for work done? Mr. Lloyd George, though he has altered his bill so often that it is very difficult to understand its present provisions (which may be reversed tomorrow), seems firmly determined to carry it through and sacrifice the doctors to the societies.

The British Medical Association is giving way on tactical grounds, and has admitted that nearly half the profession would be content with contract practice. This was at once denied, and a poll taken by the Reform Union, the result being, it is said, 95 per cent. in favor of payment for work done. In reply to the objection that this plan is difficult, if not impracticable, there is a society—the National Deposit Friendly—which works on that system, and satisfactorily to all concerned.

The voting papers for the General Medical Council have to be returned next week. In this contest the British Medical Association is pursuing its old game of using every electioneering trick to monopolize the representation by three members of its own officials. One of the branches has repudiated the assertion that it supported one of these candidates, but the repudiation was refused insertion in the journal as unfair to the "association's first attempt to run candidates"! And every one knows they have been running them from the very foundation of the council!

Yesterday at a special meeting of the council of the Royal College of Surgeons the announcement was made that Sir H. T. Butlin resigned the presidency of the college on account of ill health. In accepting the resignation the council expressed their deep sympathy with him in having to curtail the period of his presidency, and their admiration of the ability, dignity, and courtesy with which he had represented the college. The council then proceeded to fill the vacancy caused by Sir Henry's resignation. They chose Mr. Rickman J. Godlee, who is surgeon in ordinary to the king, a member of the senate of the University of London, and surgeon and professor of clinical surgery at University College Hospital, etc. The sincere wishes of the profession go to Sir H. T. Butlin for his recovery to health and strength.

General paralysis of the insane is a phrase which has been made to cover such a variety of symptoms and such complex conditions that to many who do not often see cases it seems rather a group of different diseases greatly in need of differentiation. At one time microbes and their toxins were held responsible as primary causes. Later they were held to be rather effects coming in at the period when the tissues had been so weakened as to be incapable of resisting invasion. Dr. Goodhall, at the British Medical Association this year, declared there was no reason to regard the organisms which had been detected in the tissues in any case of insanity as causes of the disease. His personal experience on the matter gave negative results. Dr. T. B. Hyslop gave an interesting lecture on the subject last month at the London Polyclinic. He has long taught that general paralysis of the insane is really made up of a group of affections similar in type, but differing in their etiology and course. Some of the types he has described at the Medical Society of London and elsewhere under the term pseudogeneral paralysis. To those engaged in asylum practice these distinctions are interesting, and have importance in relation to pathological conditions as well as to clinical appearances. But to those outside institutional work diagnosis and prognosis are, I think, more likely to absorb attention. If the general opinion now held, and which Dr. Hyslop does not question, that general paralysis of the insane is in the great majority of cases a sequel of syphilis in some form, the extreme variation it presents is what might be anticipated. The importance of detecting the coming danger at its earliest threatening can hardly be exaggerated, either from the patients' or the doctor's point of view. It is true that other causes must not be overlooked—traumatism, nervous exhaustion, or strain, and, above all, alcoholism. Where this last is known to be possible the difficulty of diagnosis is much increased. So much is this the case that Dr. Hyslop remarked that few asylum physicians could say they had never either over- or underestimated its effect. Another very difficult problem is to distinguish between general paralysis of the insane and intracranial syphilis. Yet how important the question is to the patient, and even to the practitioner! It may even occur in hereditary cases.

The last named point was aptly illustrated at the Royal Society of Medicine on the 27th of October, when Dr. P. Parkinson showed in the children's section a girl of six with symptoms that resembled

both general paralysis of the insane and diffuse cerebral syphilis so closely that the members were not inclined to give a definite diagnosis. There was a history of infection in the mother, and the child had had iritis three months before the meeting.

The medical superintendent of an infectious diseases hospital was lately subjected to the annoyance of an action for damages for alleged negligence in discharging a boy who had had scarlet fever in an infectious state. It was admitted that desquamation was not complete, but argued that in the opinion of experienced physicians less importance is attached to this than formerly. "Allbutt's system" was cited in support of this statement, and experts gave evidence to this effect and said it is now the practice to discharge such patients earlier than formerly. The patient was given printed instructions as to the danger of discharges from the nose or ears, but seems to have caught cold a day or two after going home and another member of the family became ill. The defense was successful, but the case shows the risks to which medical men are exposed.

The late Dr. J. A. Coutts, whose death was mentioned in my last week's letter as having occurred on November 1, after a short illness, was one of the foremost pediatrists in London, and second to none in diagnostic acumen. His Hunterian lectures on "Some Aspects of Infantile Syphilis," and his addresses at the Belfast and London meetings of the British Medical Association on "Functional Neuroses in Children and Non-Tuberculous Joint Disease in Children," and his work on rheumatic nodules, were all very valuable. Personally he was one of the most retiring but lovable of men, and his loss is deeply and widely felt.

Sir Samuel Wilks, Bart., M.D., F.R.S., LL.D., died on Wednesday in his eighty-eighth year, closing a long and distinguished career as a leading consultant and teacher whose work will be familiar on your side the Atlantic as well as here. He was a student of Guy's Hospital, to which he became, ultimately, consulting physician. He took M.R.C.S. in 1847 and M.D., London, three years later. He served as demonstrator and lecturer on morbid anatomy, curator of the museum, passed on to the staff as assistant and then full physician. In 1885 he resigned and was made consulting physician. In 1897 he was created baronet. In 1900, while he was president of the College of Physicians, he gave up other offices and retired from practice. His election to the Royal Society took place in 1870. He was appointed physician to the Duke of Connaught in 1877, and in 1878 to Queen Victoria. At the College of Physicians he was Harveian orator in 1879, vice-president, 1894; president, 1897 to 1900, being elected three years in succession. He represented the London University in the General Medical Council for about ten years. He had presided over the Pathological Society and that section of the International Medical Congress, and was one of the royal commissioners on contagious diseases. His valuable contributions to pathology and clinical medicine must be as well known to you as to us.

Surgeon-Major-General Robert W. Meadows, A.M.S., died yesterday in his seventy-eighth year. He qualified M.R.C.S. and entered the army in 1854, retiring in 1892. He served in the Crimea and was awarded the medal and clasp, as well as the Turkish medal. He was also in the Afghan War, 1879-80, and was present at Ahmed Khel and Urzoo, receiving the medal with clasp and being mentioned in despatches.

Dr. William Millington died on the 5th inst. at Wolverhampton, in his ninety-first year. He took M.D., Edin., with the gold medal, in 1851: M.R.C.P., Lond., 1859. He served as physician and consulting physician to the Wolverhampton General Hospital, and to the Orphan Asylum. He was also at one time connected with the Ventnor Consumption Hospital.

The Use of Whole Milk and Fat Diminished Milk in Infant Feeding. E. A. Darling.
Some Personal Observations of Southern California as a Winter Resort. G. G. Sears.
Bone Plates and Clamps in Excisions of the Knee-Joint. L. A. O. Goddu.
Sciatica: Etiology and Treatment. M. H. Rogers.

Whole Milk and Fat Diminished Milk in Infant Feeding.—E. A. Darling concludes (1) that cow's milk unmodified or modified simply by dilution or by removal of part of its fat content is a suitable food for infants; (2) that digestive disturbances in babies fed on cow's milk are usually due to an excess of fat; and (3) that the caloric requirement according to the age and weight of the infant is the best guide in calculating the amount of food to be given.

Southern California as a Winter Resort.—G. G. Sears notes that a feature of the climate of Southern California is its high humidity. The rapid and regular variations in the humidity must be considered in estimating the effect of the Southern Californian climate upon the invalid who is less able to adjust himself to the conditions than the healthy individual, while it also shortens that portion of the day which many invalids can spend out of doors. The climatic drawbacks are of slight importance to those who propose to spend a winter vacation there, provided they have resources within themselves to draw on during the occasional periods of prolonged rain, but these drawbacks must be carefully considered from the standpoint of the invalid. The climate is well suited to those suffering from arteriosclerosis, cardiorenal, or other circulatory diseases. A better climate can be found for most cases of pulmonary tuberculosis. Rheumatic affections as a class do badly.

Excisions of the Knee Joint.—L. A. O. Goddu concludes from his experience as follows: (1) the use of metal fixation methods in excisions of the knee gives the patients far less pain than without their use: (2) the holding of the cut surfaces immobile and in constant apposition is necessarily conducive to a more probable ankylosis; (3) the diseased tissue is evidently more tolerant of the presence of metals than is generally supposed.

Sciatica: Etiology and Treatment.—M. H. Rogers states that a careful examination of any case of sciatica will show that there is some trouble at or near the sacro-iliac joint, and in most cases one is dealing with a definite joint lesion. It is easily understood how the sciatic nerve may be involved if it is remembered that the sacral plexus passes directly over this joint so that any disturbance may affect the nerve. During the latter part of pregnancy, and especially after a hard confinement, sciatica of a troublesome nature is quite frequent. What happens is that under such conditions the ligaments holding the pelvis are necessarily stretched and therefore the ligaments of the sacro-iliac joints are relaxed and there is a very good chance for this joint to be relaxed. The same condition is seen also in physically underdeveloped growing girls and in women with poor musculature. The more severe cases of sciatica generally represent more definite injury to the joint. In these cases the body is listed to one side. If one is dealing with

a very acute sciatica of sudden onset, it means either an acute strain with some slight rupture of the ligaments or a displacement of the joint. If there is a strain, then the treatment would consist of fixation, as in any strained joint, which is done either with adhesive strapping or, in more severe cases, a plaster jacket. Of course rest is essential. But occasionally one meets cases in which rest and fixation will not relieve the symptoms, and it is in such cases that an immediate manipulation to reduce the dislocation often shows striking results.

Obscure Symptomatology with Tumors of the Fourth Ventricle. G. R. Lafora.
Purpura. D. Elliott and H. S. Martland.
An Unusual Case of Lichen Planus in a Negro. J. L. Kirby-Smith.

The Pharmacopœia and the Practice of Medicine.—S. Solis-Cohen would have the pharmacopœia take under its protection everything that can be applied with advantage in the medicinal treatment of the sick. As science discovers or invents new substances, animal, mineral, or vegetable, natural or synthetic; as these new substances are found to possess real therapeutical power and to be capable of standardization; and as the knowledge concerning them, experimental or clinical, becomes sufficient to permit of their practical employment, they should be taken under the wing of the pharmacopœia.

Inspection.—M. I. Knapp believes that this method is not accorded its proper place in the physical examination of the body.

Patients' Histories.—B. Robinson states that hospital case histories may be improved by an appended abstract of the history. By reading this the attending physician can ascertain whether or not he wishes to consult the complete history. It is also desirable to supplement the history with data obtained from the patient or a member of his family, as to the patient's progress after he leaves the hospital. Patients who are sent abroad for treatment should be given a written history of their case.

Sigmoidoscopy.—A. Bassler has devised a new instrument for this purpose.

Wassermann Reaction.—H. LeB. Peters notes that, in doing a routine Wassermann reaction without regard to the hemolytic content of the serum used, one is liable to error on the negative side in at least one-half the cases. In over 50 per cent. of sera the addition of artificial immune serum is unnecessary, as the requisite two units are already present in the reaction, and after the preliminary incubation of patient's serum, antigen, and complement, instead of adding sensitized sheep corpuscles, the corpuscle solution alone is necessary.

Exophthalmos in Nephritis.—L. A. Levison states that exophthalmos occurs in chronic nephritis to a much greater extent than has been supposed. The reported cases have been few and confined to the American literature. The diagnosis of exophthalmos is not always a simple matter as, in the absence of lid retraction, slight degrees of exophthalmos are very easily missed. There is no definite correlation between the various lid phenomena of Graves' disease and exophthalmos. The position of the eyeball is not constant and is influenced by the contraction of the upper lid. Exophthalmos is absent in 23.2 per cent. of cases of Graves' disease. When present, it bears no relation to the severity of the disease. Exophthalmos is not limited to the human being and has been observed in the dog, rabbit, horse, and cow. The cause of exophthalmos is not conclusively determined. The two main theories are the circulatory and muscle causes. Neither theory explains all conditions satisfactorily.

Tumor of the Fourth Ventricle.—G. R. Lafora reports a case of ependymoglioma the size of a hazel nut, and of a small angioma in the lemniscus medialis in the pons, together with a number of miliary plaques in the cortex of the brain. The clinical history was as follows: There was a cranial injury seventeen years previous to death, since which injury there was observed a change in the conduct of the patient, especially manifested in the form of attacks of depression and excitation, marked religious tendency, frequent conflicts with others. Two years ago the patient showed a self appreciation (insight) of his mental trouble. There was no history of syphilis or of alcoholism. When brought to the hospital in consequence of a recent conflict on the street, the patient appeared to be very excited during the eight days he remained in the hospital, with great motor activity, but without showing distractibility nor tendency to rapid associations of the manic type of cases. The continuous bath did not produce any beneficial effect. Later, there were rapid respiration and rapid pulse, slight cyanosis of the hands developed, without evidence of pulmonary or cardiac involvement, and these conditions continued until the patient died.

Purpura.—D. Elliott and H. S. Martland report a case of purpura fulminans.

Lichen Planus.—J. L. Kirby Smith reports a case of this rare condition occurring in a negro.

Laboratory Diagnosis of Syphilis.—By L. S. Schmitt. (See MEDICAL RECORD, July 8, 1911, page 94.)

Wassermann Reaction and Salvarsan.—By A. Keidel and J. T. Geraghty. (See MEDICAL RECORD, July 8, 1911, page 95.)

Administration of Salvarsan.—By D. W. Montgomery. (See MEDICAL RECORD, July 8, 1911, page 95.)

Salvarsan.—J. O. Hirschfelder concludes that (1) salvarsan is one of the most powerful weapons in the treatment of syphilis. (2) In the early stages of the disease it exerts its greatest influence. (3) As a rule a single injection will not suffice to cure. (4) It is best used in combination with mercury. (5) It should not be employed after other arsenic preparations have been used. (6) It should be avoided in severe affections of the brain or heart, in putrid bronchitis, in severe diabetes, and in all conditions of decrepitude. (7) It is of service in various diseases due to spirillæ.

Effect of Treatment on Wassermann Reaction.—R. W. Matson and M. A. Reasoner state that the early administration of mercury may cause a disappearance of manifestations, with little influence on the spirochetes, the organisms remaining latent for years, and under favorable conditions renewing their activity with reappearance of manifestations. A positive reaction may be made to disappear by energetic, specific treatment, and this sustains the conclusion that a positive reaction means active syphilis, even though there be no other evidence, and speaks for renewal of treatment. Patients who have been well treated give negative reactions, whereas those poorly treated give positive reactions even years later. The number of inunctions or injections of mercury or salvarsan injections necessary to convert a positive into a negative reaction varies with each patient and should be controlled by the blood examination. A positive reaction in tabes is little affected by treatment. In patients recently treated by mercury, and giving a positive reaction, the time required for a negative Wassermann with salvarsan may be much reduced. In very recent cases, or older cases not under the influence of mercury, there may be no shortening of the time.

Salvarsan.—H. Fox and W. B. Trimble, as the result of eight months' experience with this remedy conclude that (1) salvarsan is a powerful symptomatic remedy for the treatment of syphilis. (2) It acts with greatest rapidity on lesions of the mucous membranes. (3) It is of decided value in obstinate palmar and plantar syphilids. (4) The permanence of its action cannot be determined until a numbers of years have elapsed. (5) Salvarsan should be used in conjunction with mercury and cannot entirely replace this valuable remedy, except in a few selected cases. (6) The effect of salvarsan on the Wassermann reaction is less favorable than on the clinical manifestations of syphilis. (7) Its effect on the Wassermann reaction is in general analogous to that of mercury. (8) The intramuscular and intravenous methods of administration are probably of equal efficiency. (9) The intravenous method is the one of choice where rapidity of action and the comfort of the patient are factors to be considered.

Exophagoscope.—H. Lewisohn has devised an instrument built on a rectangular plan similar to the gastroscope models of Poirier and Eckstein, although it differs from these in one essential particular. Their esophageal tube was a jointed one, while the author's is a telescope formed by six small tubes which fit into one another. Each tube is 5 cm. long, and the diameter varies from 9 to 14 mm. The image is transferred at the rectangular junction by a mirror, while another perforated mirror in the eye-piece is used for the purposes of light reflection.

Ectropion.—H. E. Davis describes a new principle in the treatment of ectropion. It consists in shortening the tarsus at the temporal extremity and then attaching this extremity to the periosteum of the temporal border of the orbit on a level, slightly above the lid commissure, if the lower lid is affected, and below the commissure if the upper lid is in fault.

Pellagra.—K. H. Beall finds that in Texas this disease appears particularly to attack females. Out of 189 deaths from the disease reported to the State health officer only thirty-six were males. The author does not believe that the females are less susceptible or more resistant but thinks that for some reasons they must be more exposed. Another interesting fact is that of the thirty-six male deaths there were only seven between the ages of 20 and 50, or those years in which they would be most away from home. This suggests to the author that the agent may be active in the daytime only and be something about the house or home.

Pellagrous Symptoms in Fowls.—C. C. Bass states that he has succeeded in producing pellagrous symptoms in a fowl by feeding the latter with cornmeal inoculated with cultures of bacteria obtained from the stools of pellegra patients.

Poliomyelitis.—S. Flexner and P. F. Clark state that the virus of poliomyelitis has been detected outside the central nervous system, including the intervertebral ganglia, of affected human beings and monkeys. The only place where it occurs with any constancy, however, is in the nasopharyngeal mucosa. The virus also exists in the tonsils and pharynx of human beings who succumb to poliomyelitis as constantly as in monkeys after any intracerebral inoculation. It has not been found in the blood of human beings, though it has in that of monkeys at the height of the acute disease, when large quantities are withdrawn and injected intravenously into a healthy monkey. The cerebrospinal fluid is devoid of demonstrable virus at the onset in human beings and in monkeys, though it has been detected in that of monkeys before the onset of paralysis and during the incubation period. The authors have succeeded in implanting on monkeys all the ten strains of human virus with which they have experimented. The latter infect monkeys less readily than do the modified or monkey strains and the experimental disease produced by them is less severe and fatal, but after becoming adapted to the monkey the paralytic disease appears in more severe form. The artificially evolved monkey strains of the virus may have lost in some degree the power to infect human beings.

Salvarsan and Mercury.—J. S. Eisenstaedt believes that one should look on salvarsan as an adjuvant to mercurial treatment, and accord it a place in the therapeutics of specific disease, but that one should carefully select the cases for treatment with it. Also, after having obtained benefit from the preparation, one should hope for the maintenance of this good effect only by the use of classical routine mercurial therapy.

Pellagra and Salvarsan.—P. M. King and A. J. Crowell report satisfactory results in the treatment of cases of pellagra with salvarsan.

Pellagra.—T. Frazer reports a case of this condition.

Diet and Pellagra.—G. A. Zeller states that the maize theory has tenaciously survived for a century and a half, and has, in the judgment of those who enter the field of study with open minds, done much to retard the true solution of the cause of the disease.

Cholecystitis and Cholelithiasis in Relations to Pregnancy.—By L. H. Branson. (See MEDICAL RECORD, July 8, 1911, page 106.)

Ruptured Pus Tube.—A. P. Stoner reports a case of diffuse septic peritonitis resulting from the rupture of a pus-tube.

Remarks on the Modern Methods of Diagnosis as Illustrated by a Case of Tumor of the Lung. N. Dalton.

Recent Developments in Syphilis.—H. C. French reviews this subject.

Urinary Tuberculosis.—S. West states that the first symptoms that bring the patient under observation are usually (1) increased frequency of micturition; (2) occasional hematuria; and (3) pain, vesical or renal as the case may be. The cases fall into two clinical groups according

as the symptoms are those of cystitis or pyelitis. The symptoms of subacute cystitis of long standing in a young person would excite grave suspicion of tuberculosis. It would be necessary to exclude gonorrhea and calculus as causes, and new growth too, though this would be unlikely. Tuberculosis would be almost certain if this condition were found in the testicle, to which it might be secondary. The kidney symptoms are pain in the loin and tenderness on pressure, or a tumor which may be felt or demonstrated by the *x*-rays. In this case calculus especially, and possibly new growth, would have to be excluded, as well as *Bacillus coli* infection. If with symptoms of cystitis there are renal symptoms as well, the probability of the kidney being also tuberculous is very great.

Wassermann Reaction in Paresis.—J. P. Candler, as the result of his clinical studies, concludes that a positive Wassermann reaction was obtained with the cerebrospinal fluid of 67 out of 69 cases of paresis (a percentage incidence of positive reactions of 97 per cent.).

Epidemic of Conjunctivitis.—J. P. McGowan and W. Macrae Taylor state that from five cases of an epidemic of conjunctivitis in an institution they have obtained in each case a pure culture of a Gram-positive diplococcus, with elongated and lancet-shaped elements. The superficial examination ordinarily employed in ophthalmic practice is insufficient to distinguish it from the pneumococcus, from which it really differs markedly.

Intestinal Obstruction Caused by Gallstones.—E. Owen reports a case which at first sight was very like one of appendicitis, showing, as it did, general distress, abdominal pains, a tender mass in the right iliac fossa, and vomiting. But there was absence of that constant sign of appendicitis—rigidity of the lower part of the rectus and of the neighboring muscles.

"Comforter" Caries.—E. H. R. Harries describes a condition of asymmetrical hypertrophy of the upper lip and caries of the central incisors present in young children as the result of indulgence in the "comforter."

Blood in Bilharziasis.—H. B. Day concludes that bilharziasis is characterised by a slight general leucocytosis due to a considerable increase in eosinophile and large mononuclear cells, the polynuclears being diminished. 2. These changes are roughly proportional to the intensity of the disease provided the patient's general condition is good. The presence of grave anemia, sepsis, or complicating disease obscures these changes, which reappear on improvement. 3. Secondary anemia is present to a moderate degree in most cases. Even when the red corpuscles show no reduction in numbers there is a loss of hemoglobin. 4. Profound anemia may be caused by excessive loss of blood, prolonged suppuration, and especially chronic diarrhea. 5. Bilharziasis is the commonest worm infection in Egypt and is responsible for most cases of moderate anemia in children. 6. Ankylostomiasis incapacitates a larger proportion of the population than does bilharziasis. 7. Ankylostomiasis is a much more frequent cause of severe anemia than is bilharziasis. The term "Egyptian chlorosis," if used at all, should not be applied to the secondary anemia produced by bilharziasis. 8. The combination of both infections or the association with other diseases, such as cirrhosis, tends to aggravate the anemia.

Treatment of Syphilis.—W. W. Bayly notes that if rapidity of change of reaction be taken as a test of efficiency of treatment he would place salvarsan first, inunction or intramuscular injection of insoluble mercurial compounds second, and mercurial pills and suppositories a bad third. He considers that the results obtained suggest the advisability of combined salvarsan and mercurial treatment.

Tumor of the Lung.—N. Dalton reports a case of sarcoma of the lung, the points of interest in which are the apparent acute onset and the rapid growth of the tumor and the high leucocyte count and the high fever which made the case appear one of abscess. A leucocytosis of 38,800 is most rare in a case of tumor. This may be explained by the intense pneumonia which was found after death. In fact, the patient had septicemia as well as a rapidly growing and a rapidly degenerating tumor. Still, the leucocytosis was a source of error. The *x*-ray department was, in this case, more useful than the laboratory.

The Use of Our Authority. S. Paget.
The Factor of Commonness in the Diagnosis of Cancer. W. Gordon.
Torsion of the Great Omentum. A Case Clinically Resembling Ovarian Cyst with Twisted Pedicle. J. P. Hedley.
A Case of Antenatal Pneumonia. A. T. I. Macdonald.
A Case of Hemochromatosis, or Pigmentary Cirrhosis of the Liver with Glycosuria. M. D. Roberts.
Removal of the Eyeball: A Quick and Easy Method. W. Robinson.

Authority and the Medical Profession.—S. Paget notes that physicians are bound by their calling to speak with authority on subjects such as food and drink, vaccination, animal experimentation, and Christian Science.

The Factor of Commonness in the Diagnosis of Cancer.—W. Gordon, on the basis of statistical investigations, concludes that by far the commonest of all cancers are cancer of the stomach in both sexes and cancer of the uterus and breast in women. The next commonest come cancer of the liver, rectum, and intestines in men and women. Next come cancer of the esophagus and tongue in men. All the rest are much less common. The rarest of all is cancer of the heart and pericardium. Most organs are more often cancerous in men than in women The older the patient from 45 onward the greater the relative chance of a cancer being intestinal. The older the patient from 35 onward the less the relative chance of a cancer being pancreatic. The older the patient the less the relative chance of a cancer being renal as compared with the chance of its being vesical (primary cancer of the urethra is extremely rare). In women the chances of renal and vesical cancers are more nearly balanced than in men. In men the older the patient the greater the relative frequency of prostatic cancer.

Torsion of the Great Omentum.—J. P. Hedley reports a case of this condition in which the signs and symptoms very closely resembled those produced by the twisting of the pedicle of an ovarian cyst.

Antenatal Pneumonia.—A. T. I. Macdonald reports the case of an infant that died twenty-eight hours after birth. The mother had pneumonia at the time of delivery. Autopsy in the infant showed a condition of lobar pneumonia. From the advanced inflammatory changes present in the fetal lungs so soon after birth it is probable that the pneumonic condition originated *in utero*. Had the pneumonia arisen from insufflation of liquor amnii or vaginal discharge before delivery it would have had a lobular rather than a lobar distribution. In this case there was no insufflation of morbid material, rupture of the membranes preceding the birth of the child by twenty minutes only.

Hemochromatosis.—M. D. Roberts report a case of this condition.

Removal of the Eyeball.—W. Robinsson describes a quick method of performing this operation.

Berliner klinische Wochenschrift.

November 6, 1911.

Eclampsia.—Wolff-Eisner believes that the time is favorable for the accumulation of statistics on eclampsia to supplement the laboratory and clinical data which have now become so numerous. He would address circular inquiry blanks to practitioners and would press into serv-

ice the veterinarians, for it is claimed that bitches and cows suffer from puerperal affections which may or may not be analogous to human eclampsia. Experiments on animals should also be made along certain special lines, especially in regard to the anaphylactic theory. In the dog the eclampsia-like affection yields readily to morphine. The so called eclampsia of cows is not a convulsive but a paralytic affection and appears to be due to a special oversensitiveness of the vasomotor center. The anaphylactoxic substance may be derived from the newly formed colostrum, or more literally from the casein content of the latter. The eclampsia of cows may be readily cured by the insufflation of air into the milk ducts. The rationale of this treatment may however be bound up with a reflex stimulation of the vasomotor center. Some of the questions to be addressed to practitioners are as follows: How many cases of eclampsia have you seen? What was the parity of the subject and what the character of the next birth? Were second cases milder or more severe than first ones? What was the mortality of first and second cases? What was the effect of emptying the uterus? How often were there evidences of neuropathy, particularly of vasomotor instability, in the mother, and in her ascendants and descendants respectively? The author anticipates that the data to accrue from such a research would point to an anaphylactic disease. Already considerable clinical testimony has accumulated along this line. Much problematic morbidity and mortality during gestation can only be explained by anaphylaxis. Again, the general semeiology of the latter runs parallel with the morbidity of gestation (exanthema, fever, swollen lymphnodes and joints, leucopenia, edema, albuminuria, emaciation, leucocytosis, paralyses, convulsions, headache, asthma, etc., etc.). Naturally only a small portion of the entire complex occurs in any one individual for a given cause. Much depends on the forthcoming statistics concerning second and subsequent cases of eclampsia, which with the anaphylactic theory should be more severe than the first, although not invariably so.

Progress in the Treatment of Diphtheria.—Meyer considers in order the curative effects of serum, the prophylactic effects of the same, and the non-specific treatment. It has been abundantly shown that the intravenous injection is superior to the subcutaneous method, and should be preferred in all cases which give early information of severity, such as hemorrhagic forms of the disease. The technical difficulties, however, are too great to permit of routine application. If the vein cannot be exposed properly the intramuscular injection should at once be practised, and must suffice whenever the intravenous method seems impracticable. If injected in maximal high doses, antitoxin by the intramuscular route may have the curative power of intravenous injections. But if a massive early intramuscular dose is inoperative it may be best to make the next injection into a vein, and the latter would be the method of necessity in cases seen late. Evidently a practitioner of expert knowledge might need to be summoned for an intravenous injection. Serum disease is variously combated with thyreoidin, aspirin, and calcium salts. Under large, promptly given and promptly acting doses many favorable statistics confined to grave types of disease are accumulating. On the other hand prophylactic injection seems to be overdone, and many authorities would restrict its use to certain categories of those exposed. Serum disease is by no means confined to those who had already received an injection. Sensitiveness to horse serum is found in many who spend their time in stables, while some people are so supersensitive in this way that a mere temporary exposure may cause asthma or other vasomotor disorder. Asthmatics of any kind and those with respiratory affections in general seem predisposed to severe serum disease. The immunizer should have everything ready to treat sudden collapse after a serum injection, rare as the need for it may be. There have been no advances in the nonspecific treatment of diphtheria which have received general acceptance.

The Rôle of the Spleen in Cancer Immunity.—According to Braunstein recent experiments are showing a possible protecting influence of the spleen in securing cancer immunity. This organ is very rarely the seat of metastases, and if cancer tissue is implanted therein it soon dies. Splenectomized animals are not resistent to cancer inoculation from heterologous sources. The spleen appears to be the chief seat for the manufacture of antibodies and splenic extracts seem to confer a considerable degree of immunity when obtained from animals affected with cancer.

Münchener medizinische Wochenschrift.

October 24 and 31, 1911.

Cerebral Influenza.—Stepp discusses the cerebral localizations of influenza, which often impose themselves on the practitioner as diseases *sui generis*. Our knowledge of them has not kept pace with what we know of other phases of this polymorphous affection. One author mentions meningitis and focal encephalitis; another describes a hemorrhagic encephalitis. Secondary consequences are aphasia and monoplegias. Analogous lesions occur in the cord. The author narrates three personal cases. In the first, in a healthy subject, influenza presented a typical onset. By the second day, partial left facial paralysis had developed as a forerunner of complete left hemiplegia. Ultimately use of the leg returned, but the arm became contractured. The second patient similarly came down with typical influenza, and a violent bronchitis persisted for fourteen days. Three weeks after the onset right facial paralysis developed, to be followed at once by complete right hemiplegia. This subject, like the first, was perfectly sound when first attacked. After another three weeks left hemiparesis developed, the leg alone showing complete paralysis. The left side recovered completely, but on the right side, which had suffered least, the return to the normal had not been complete. The third case was of the same type, but diabetes was present. In the absence of autopsy findings the author is forced to suppose that influenza—bacilli or toxins—can attack the finer capillaries of the brain with production of a serious edema and some extravasation of blood. Such lesions may end in complete resolution.

Fatal Sepsis Complicating Varicella.—Blühdorn reports a case of streptococcus sepsis of which the exciting cause was varicella. The lesion which first appeared suggested a suppurative parotitis of one side, which could be a natural complication of almost any acute infectious disease. It soon became apparent that the lesion was purely edematous. It was incised and drained. There were no evidences of local infection at first but severe general sepsis developed. Hemolytic streptococci were found in the blood and eventually in pus which formed in the wound. Autopsy was not obtained. From a survey of the literature and by legitimate deductions from the case itself it seemed probable that the sepsis was otogenous.

Disappearance of Warts after Ablation from Opposite Hand.—Genewein first mentions a case in which excision of a solitary wart on one hand was at once followed by spontaneous disappearance of all the warts on the other hand. On a subsequent occasion removal by caustic of a solitary wart on the back of the hand was followed promptly by disappearance of a nevus on the bearded chin. The author then deliberately tested the matter on a third patient who had numerous warts on both hands. Removal of those on one side by trichloracetic acid was followed by spontaneous disappearance of the warts on the other hand. Rothbaum also states in a com-

mentary on Genewein's article that he had an opportunity of verifying these cases by experiments from which it appeared that whenever a wart on one hand was burned off improvement very speedily followed in warts on the other hand.

Muscle Excitability in Tetany.—Schultze has studied the mechanical muscle excitability in adults with tetany and finds that certain muscles show a peculiar behavior. The latter consists in a prolonged contraction, which is evident especially in the tongue and facial muscles. The contraction is not continuous but consists of serial twitches with brief, regular intervals. This behavior serves to differentiate tetany from myotonia. It is known that in the latter affection percussion of the tongue causes a pronounced circumscribed muscle contraction, which causes a recess or depression to appear in that organ. The latter by percussion in separate areas may be transformed in general contour. The author found what he at first regarded as the same induced phenomenon in tetany. Study of other muscles showed that analogous phenomena could be obtained in the orbicularis palpebrarum, nasal muscles, etc. The contraction persisted for a minute at times as a result simply of percussion and without invoking the electric current. These contractions are obtained by direct percussion over the muscles; and while in some cases the entire musculature supplied by the facialis may apparently be reflexly excited, there is no necessary connection between these reactions and Trousseau's phenomenon, although the latter may usually be induced. From the behavior of other muscles it is also inferred that the tongue phenomenon in tetany differs from that in myotonia although further research is required to differentiate fully. In the sole tetany case examined by the author the tongue contraction persisted for more than a minute, for so long a period of time, indeed, that the affected organ could be photographed.

Cancer Statistics from Baden.—Werner draws numerous conclusions from the recently compiled cancer statistics of Baden. The cause should not be biologico-hereditary, and physical, chemical, and parasitic factors must be no longer relegated to the background. Grouping of cases cannot well be set down to mere contact infection, but to the general residential surroundings. Direct hereditary transmission and misplaced embryonal residues are unable to throw light on the genesis of cancer as a whole. Relative frequency of the disease by individual territorial localities should be the means of throwing light on the nature of cancer. It is conceded that the latter is distributed in much the same manner as would be the case were it an infectious (not contagious) disease. To such an extent is this so, Werner contends, that we can no longer avoid the conclusion that there must necessarily be a parasitic cause for at least the majority of all cases of cancer.

Treatment of Hemophilia.—Schilling relates a single case of favorable result in a boy aged 5, whose brother and mother were also bleeders. The degree of hemophilia did not appear to be high. Other members of the family seemed sound. The mother was not an habitual hemophilic but nearly bled to death on one occasion. The older brother suffered constantly from purpura hemorrhagica. The patient first showed incoercible hemorrhage from the gums. Hemoglobin fell to 25 per cent. Death being impending, direct transfusion was practised. High fever resulted but by the third day the patient was normal and bleeding had ceased. Bearing in mind the temporary character of the improvement which sometimes results in these cases the author used *x*-rays every third day over the spleen and long bones, exactly as in the case of a leucemic patient. The hemoglobin went up to 60 per cent. and the blood count also showed a marked regeneration picture.

Deutsche medizinische Wochenschrift.

November 2, 1911.

Treatment of Cancer.—Czerny regards as all-important the answer to this query: is cancer in any way amenable to therapeutic influences? If it is so, ever so slightly and transitorily, we may experience some hope from research concentrated along such lines. He discusses all our resources in succession, beginning with the knife, which does not guarantee against recurrence even under favorable circumstances. In cases where recurrence is most to be dreaded he uses the electric arc light in the form of the socalled Forest's cold cautery, and high-frequency Herzian waves. He has replaced fulguration with diathermy to a large extent. In using these substitutes for the knife he is of course actuated by the belief that the thermopenetration which results may tend to devitalize the cancer cells. Radiotherapy, including both radium emanations and *x*-rays, finds a very wide field of application, since both kinds of rays are able to destroy tumor cells. Tumors at first inoperable have thereby been rendered operable, and the influence of the rays is in all respects palliative. We are thus far only in the empirical stage of this form of therapeutics. There is considerable to be hoped for along such lines as chemotherapy, toxin and antiserum therapy as soon as experimental pathology can furnish us a sound rational basis. In conclusion the author relates a number of cases in which the cold cautery and radiotherapy were used very successfully in cases of cancer with bad outlook.

Parkinson's Disease.—Schultze considers some aspects of paralysis agitans, with especial reference to nosology. The disease may be present without paralysis and without trembling. The so-called palsy is really a helplessness due to muscular rigidity. True paralysis only occurs late in the disease. The author would therefore continue to call the affection Parkinson's disease. With a few others he has noted the frequency of the so-called Stellwag symptom—involuntary snapping of the eyelids at long intervals—in this condition. He found it present in over half his patients. Kocher found about the same incidence of this symptom in Basedow's disease. The phenomenon seems to be due to an increased tonus in the levator palpebrarum corresponding to the general muscular rigidity in Parkinson's disease, although the same result might occur from hypotonus of the orbicularis palpebrarum. Tremor when at rest, so characteristic of Parkinson's disease, may constitute the sole evidence of the latter. In such a case we look on the disease as present in an abortive form. In rare instances in the young differentiation from multiple sclerosis becomes very difficult. Dependence is usually placed on the character of the tendon reflexes, but these may sometimes be increased in Parkinson's disease and the author has even found the achilles reflex absent. The thyreogenous theory of the disease receives some slight special support from the presence of Stellwag's symptom in both it and Graves' disease. The blood count is said to be the same for both affections, and tremor is conspicuous in each. Moebius claimed to have seen the two syndromes occurring in the same individual.

Paroxysmal Hemoglobinuria.—Grafe relates a case of this affection which differs perhaps in certain respects from any upon record. The patient was a child with hereditary syphilis. The paroxysms were in no wise affected even by the widest variations in external temperature. Blood tests gave conflicting results. The conception of this affection has heretofore been a hemolysis determined by the action of cold external temperatures on a labile vasomotor system. Withdraw the element of cold and there is nothing to account for the vasomotor reaction. A psychical element can be excluded. We can only say provisionally that the hemolysis occurred spontaneously from conditions originating in the blood itself.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

PERSONAL HISTORY.

Diseases of the Digestive System.—In this class of diseases, more than any other probably, there are conditions in which difficulty in diagnosis is frequently encountered and in which grave and menacing disorders may be associated with and masked by symptoms pointing apparently to comparatively unimportant ailments. At the time of the examination all signs of these disturbances may have departed, and yet the primary trouble may remain dormant or is liable to recur. With these possibilities in mind, even though the examiner has gathered all the history obtainable and reports a negative result from his examination, a medical director will often find it necessary to ask the applicant to furnish a certificate from the physician who attended him during the illness and who is therefore the only one in a position to give a well-defined idea of the real nature of the trouble. After all these precautions have been observed, so much doubt may still remain that the applicant will be postponed or rejected in order that the company may be given the benefit of the doubt.

Dyspepsia, Indigestion, Biliousness.—Ascertain the frequency, duration and cause, and the date of the last attack. These disturbances, so common in America, are not usually regarded as worthy of much comment, and in most cases this attitude is justified. When, however, the attacks come frequently or the condition is more or less chronic, they should be looked upon as an important factor in the selection of risks, especially if the weight of the applicant is under the standard or there is a poor family history. Dyspepsia or indigestion may be an early symptom in tuberculosis or various organic diseases, but the chief point of interest, probably, is whether or not the attacks are indications of or associated with appendicitis or affections of the gall bladder.

Given, then, a history of dyspepsia, indigestion, or biliousness, the examiner should use his best efforts in trying to find out whether the trouble was primary or whether it was secondary to one of the more serious maladies. The medical staff at the home office will often want a certificate from the attending physician in cases of fairly recent disorders of the digestive system in order that gall stones and appendicitis may be eliminated as far as possible.

Hematemesis.—Give the number of times the applicant vomited blood and the date of each occurrence. The conditions which cause hematemesis are so serious and apt to recur, even after recovery has apparently taken place, that a long period should elapse before such a risk will be accepted.

Diarrhea.—Report the date, duration, frequency, and cause if the attack was a prolonged one or if there were several of them.

Appendicitis.—Give the date and duration of each attack, and the date of the last attack. If there has been an operation, ascertain the date, whether the appendix was removed, whether there was pus, whether there were adhesions and, if so, how extensive, and whether there was healing by first intention.

When there have been one or more well-defined attacks it is easy to get a true history, but unfortunately many of the cases develop insidiously and without the typical signs. A number of cases occur to the writer as illustrations, but the following instances will be sufficient to emphasize the point:

1. A physician was affected, as it seemed to him and his medical friends, with severe intestinal indigestion and fermentation for about a year, the malady refusing to yield to remedies and out-of-door life. At the end of the year the trouble resolved itself into a fairly typical attack of appendicitis. The appendix when removed gave evidence of an inflammatory condition of long standing and the intestinal indigestion began to depart on recovery from the operation.

2. Another interesting case which came under the writer's observation and caused considerable comment at the time is that of a young man with a history of typhoid fever one year previous to his application for insurance. The typhoid was followed by mild attacks of intestinal cramps of an hour's duration about once a month. The physicians, men of reputation, believed that the cramps were caused by an irritable colon as a sequel to the typhoid fever. Two years after the supposed typhoid an operation revealed the presence of chronic appendicitis with extensive adhesions. The patient was relieved of his disagreeable symptoms by the operation.

3. This case is one of common occurrence. The applicant admitted in an examination in August, 1911, that he had some biliousness in the previous year. A certificate from the attending physician was asked for and from this it was learned that the so-called biliousness consisted of two attacks of mild catarrhal appendicitis with some colic.

The subject of appendicitis has been treated at some length on account of the atypical courses followed by the disease and the high mortality experienced as a result of it, notwithstanding the perfected technique of abdominal surgery. The examiner cannot be too searching in his questions and examination whenever the applicant admits gastric or intestinal pains or any other symptom, no matter how mild, pointing to trouble in the gastrointestinal tract.

Colic.—Recurrent attacks of abdominal pain or even one attack when recent should suggest appendicitis, gall stones, renal colic or plumbism, and lead the examiner to be very inquisitive in eliciting the personal history with this probability in mind. Full details as to dates, duration, severity and cause, as well as the date of the last attack will be required.

Disease of the Liver.—Aside from cancer and cirrhosis, the serious forms of liver troubles are seldom met in this country. A history of gastroenteritis, the so-called bilious attack, is unimportant unless it was severe, protracted or recurrent, and its association with some condition of a graver nature cannot be excluded.

Jaundice.—Ascertain the dates, frequency, duration, severity and cause; also whether there were other symptoms such as pain or tenderness. The examiner should never regard these cases lightly, as too frequently when it was assumed that the jaundice was due to a catarrhal condition it was found later that gall stones were the real cause. The failure to find the calculi in the stools is by no means positive proof that they were not at the bottom of the trouble, as it is such a simple matter for them to escape discovery.

When the jaundice was due to malaria this should be reported, as it usually affords evidence of a type more severe than the ordinary.

Gallstones.—Gallstones are a source of constant danger as long as they remain in the gall-bladder or common duct. To make matters worse, it is not always easy to determine whether they are present or not. Physicians familiar with the work in any of the large hospitals recognize the fallibility of even the best diagnosticians through the unexpected revelations of the surgeon's knife at times, and affections of the gall bladder and ducts are probably responsible for as great a number of errors as those of any other organ in the abdominal cavity. How difficult, then, will it be to discover the underlying cause in some cases in which the indications, merely some passing pain, digestive disturbance, slight tenderness apt to escape notice, or a little jaundice, were too indefinite and vague to occasion more than a casual visit to the attending physician. And yet in these cases, as well as in those with well-pronounced symptoms, the stones are a menace to life as long as they remain. In consideration of the facts presented, the examiner should be unusually persistent and careful in getting at the full history of any one of the symptoms, however mild and vague, which may have indicated the presence of hepatic calculi.

In operative cases, it will be necessary to have the applicant procure a statement from the surgeon as to the part involved. It seems to make but little difference from a life insurance point of view whether the gall bladder was drained or removed. When, however, the common duct was involved in the incision, the case is looked upon as more serious and as one in the later stage of gall-stone disease with dilated ducts into which the stones may slip out of sight, with denser adhesions to surrounding structures and with a greater liability to malignancy or other serious complications.

The best way to treat these cases at the home office is to refuse to issue insurance when no operation has been performed until at least five years have elapsed since the attack. If there have been several attacks it may be wiser to lengthen the period. The risk may be assumed after a shorter period when there has been an operation for drainage or removal of the gall-bladder, but a much longer time should elapse when the common duct was invaded.

Hemorrhoids.—These will require no comment, whether external or internal, unless considerable blood is lost. When the applicant has had an operation performed at an age of forty or older, he may be required to furnish a certificate from his attending physician as to whether or not there was any suspicion of malignancy.

Fistula.—It must always be definitely settled whether there was any suspicion of tuberculosis. The date and duration should be given.

Tapeworm.—Ascertain if the head passed away at the time of removal. If the head was not found, it is better to wait a few months before accepting the risk.

The Use of Alcohol and the Life Insurance Risk.—By Dr. T. F. McMahon. (See page 1121.)

Occupation Hazards.—See page 1131.

The Association of Life Insurance Presidents will hold its fifth annual convention at the Hotel Astor in New York City on December 13 and 14, with John R. Hegeman, president of the Metropolitan Life Insurance Company, as chairman.

The Families of the Tuberculous.—As a contribution to the discussion of the action of heredity in the etiology of tuberculosis, José Codina Castellvé of Madrid gives the results of an inquiry into the antecedents of 135 cases of tuberculosis occurring in his practice. Of this number 56, or 41 per cent., either asserted that their parents were healthy or were unable to give a family history. The remaining 79, or 59 per cent., gave a family history of tuberculosis or some other pathological condition presumably more or less active as a predisposing cause of the disease from which they suffered. Of these patients 66 per cent. were males, 34 per cent. females. Of the diseases of the grandparents, when these could be ascertained, the most frequent was tuberculosis, which occurred in 31 per cent. In these cases the disease affected the parents as well. In more than half of the cases giving a pathological family history the disease from which the parents suffered was tuberculosis, the father being affected more frequently than the mother in the proportion of about 3 to 2. Next to tuberculosis the most common affections in the antecedents were intoxications and chronic infections and diseases of the respiratory tract. More than half of the children of tuberculous parents (52 per cent.) suffered from pulmonary tuberculosis, and if we take into account the extrapulmonary localizations of tuberculosis and other more or less related affections, such as adenoid vegetations, scrofula, and lymphadenoma, the percentage of diseased children of the tuberculous was 69. Tuberculosis occurred in the uncles and aunts of the patients, the parents being unaffected, in only 16 per cent. The cases of tuberculosis affecting both husband and wife were, in Castellvé's experience, very few in number.—*Gaceta Médica Catalana*, October 15, 1911.

Race Biology and Life Insurance.—Grasse says that among Caucasian races the higher classes are not as fruitful as the lower classes, while the opposite is the fact among Chinese, for instance. The disadvantage of the latter condition consists in the progressive "descent" of members of the higher classes to the lower classes, such members being physically and mentally inferior. This results in deterioration of the race. Among Caucasian races, on the other hand, the danger is in too great a diminution of fertility in the higher classes, so that even mediocre individuals from the lower classes are called upon to do the work of the former. A great many social, political, and economic circumstances have taken the places of natural selection in the growth and development of a strong race. The problem of race biology consists in determining the number of individuals that should be brought forth into a society, and the work of strengthening such elements in the race as preserve its vitality and its capacity to develop to the full extent in meeting the demands of the struggle for existence. So far as insurance is concerned, many genealogical trees, family histories, etc., give data casting much light upon the expectation of life and health of individuals. Another concern of race biology is to prevent the union in marriage of sickly or otherwise unsuitable individuals, and here life insurance can play a very important rôle. The public must be simply educated to expect that every prospective bridegroom and bride should be insured before marriage; if either one were denied insurance by the companies, it should be his or her duty to prove to the parents of the bride or the groom, as the case might be, that the grounds for refusing insurance were not equally strong grounds against entering into the married state. If this custom, Grasse says, should become universal, life insurance would indeed become a great factor in the preservation of the strength and health of the race.—*Blätter für Vertrauensärzte der Lebensversicherung*, September and October, 1911.

Book Reviews.

Die palpablen Gebilde des normalen menschlichen Körpers und deren methodische Palpation. Nach eigenen Untersuchungen an der Leiche und am Lebenden, von Dr. Toby Cohn, Nervenarzt in Berlin. III. Teil: Hals und Kopf. Mit 33 Abbildungen, davon 18 im Text und 15 auf 7 Tafeln. Berlin: Verlag von S. Karger, 1911.

The first two volumes of Dr. Cohn's special study of the palpable structures of the human body dealt with the upper and the lower extremities. The present volume considers the face and neck. Dr. Cohn takes each separate region of these divisions of the body and describes the parts that can be seen, then palpated, as well as nerves, vessels, etc., that are found in intimate relation to the palpable organs. The thoroughness of the work is shown by its extent, over five hundred pages being devoted to the subject. Its importance to the surgeon and especially to the neurologist is manifest: it is a regional anatomy *de luxe*, pointing out minutest subdivisions of body parts that can be found by careful palpation. The complete work will form a monumental labor, an example of the thorough and painstaking medical study, so characteristic of the German physicians.

Education. How Old the New. By James J. Walsh, M.D., Ph.D., Litt.D., Dean and Professor of the History of Medicine and of Nervous Diseases at Fordham University School of Medicine; Professor of Physiological Psychology at the Cathedral College, New York. Price, $2.00. New York: Fordham University Press, 1910.

This is a volume of addresses, dealing with education in the past. Much of what the author states in this book is worthy of study, and readers of his previous works will know what to expect. Perhaps the best address is that on the "Origins in American Education," which shows the excellent work that was being done in Spanish-America long before there was any university in what is now known as the United States. Other addresses of interest to physicians are those on "Medieval Scientific Universities," "The Medical Profession for Six Thousand Years," and "University Medical Schools." The address on "New Englandism" seems to strike a discordant note, and while quite entertaining to "foreigners" is very likely to displease "New Englanders." It is possible that the author does not intend all of his statements to be taken seriously and literally, for example: "I recommend the reading of Juvenal to the college young woman of the modern time, not only for its classic but for its social value." But perhaps he forgets the very satire from which some of his previous quotations are taken. Those who are acquainted with this satire (the sixth) would hardly select it for the "college young woman." We would like some more explicit reference to the statement on page 127 that "various methods of anesthesia, one of them by inhalation . . . were invented" in medieval times.

A Text-Book of Physiology: for Medical Students and Physicians. By William H. Howell, Ph.D., M.D., LL.D., Professor of Physiology, Johns Hopkins University, Baltimore. Fourth Edition. Revised. Cloth, $4.00 net; Half Morocco, $5.50 net. Philadelphia and London: W. B. Saunders Company, 1911.

While the mosaic style of book making appears to be growing in poularity, and the plan of having many authors contribute small sections of a subject has undoubted advantages, the difficulty of securing homogeneity in the result is admittedly great. Almost invariably disconcerting gaps or repetitions occur, and from the standpoint of the student, at least, something akin to the skill of the expert in picture puzzles is required to derive from the separate fragments a uniformly proportioned representation of an entire department of knowledge. The "one man treatise," therefore, whatever it may lack in minuteness of detail, will always remain the most desirable text-book for the beginner, whose needs demand above all an intelligent correlation of the various categories of facts to which he is being introduced. This is especially true of physiology, which shares with anatomy the responsibility of supporting the whole fabric of the medical edifice, but differs from the latter in the complexity of the units of which it is composed. Howell's text-book has already been recognized as ranking with the masterpieces of Hermann, Foster and Tigerstedt, and in its present edition it takes first place as a sufficiently comprehensive but readily assimilable presentation of the entire domain of physiology in its most modern developments. Recent advances have been most conspicuous perhaps in the provinces pertaining to the mechanism of circulation and heart action, the activities of the ductless glands, and the principles of nutrition and metabolism, and the chapters on these topics may be singled out for especial mention as being fully representative of the progress that has been made. Although the desirability of a certain degree of dogmatism in dealing with students has not been lost sight of, in the treatment of controversial points the author constantly leaves sufficient latitude to the reader's discriminaion to stimulate independent thought and indicate the necessity for further investigation. In comparison with the distinguished characteristics of the text the illustrations and typography must take a minor place.

Experimentelle Grundlagen der Chemotherapie der Spirochætenkrankheiten, mit besonderer Berücksichtigung der Syphilis. Gesammelte Abhandlungen von Prof. Dr. Paul Uhlenhuth, Geh. Reg.-Rat und Direktor der bacteriologoschen Abteilung im Kaiserlichen Gesundheitsamt Berlin. Mit vier Tafeln. Price, 16 marks. Berlin and Vienna: Urban & Schwarzenberg, 1911.

This volume contains twenty-three papers published by Uhlenhuth between 1907 and 1911, dealing with the experimental study of diseases caused by spirochetes and their therapy. Most of them concern the action of atoxyl and its derivatives, especially its combination with mercury, a preparation in which Uhlenhuth placed much hope, that has been but little realised. Several of the later papers deal with Ehrlich's work in chemotherapy and give some consideration to salvarsan. Uhlenhuth cannot hide in these papers the chagrin of a man who has devoted much time and ability in developing scientific chemotherapy, only to see his own results eclipsed and almost forgotten by Ehrlich and his school. This volume, therefore, is of most interest to the medical historian tracing the development of a new departure in therapeutics; to the practitioner it can have but a passing interest.

Hygiene for Nurses. Theoretical and Practical. By Herbert W. G. Macleod, B.Sc., M.D., M.S. Edin., M.R.C.P. Lond., D.P.H. Lond., D.P.H. Camb. With Illustrations. Price, $1.50. New York: William Wood & Company, 1911.

This unpretentious little volume contains the most important facts in hygiene which are essential to a nurse in her daily work. The subjects discussed are: Air, Ventilation, Heating and Lighting, Water, Drainage and Sewerage, Disposal of Sewage, Infection, Disinfection, Food and Milk, etc., and Personal Hygiene (including Baths, Clothing, Games, Exercises, Habits, Fashions). The book is well written, the language is simple, the statements are concise and accurate; the volume cannot fail to be of practical value to every nurse.

Cesare Lombroso. A Modern Man of Science. By Hans Kurella, M.D., Author of "Natural History of the Criminal," etc. Translated from the German by M. Eden Paul, M.D. Price, $1.50. New York: Rebman Company, 1911.

This book is something more than a biography. It is a critical and sympathetic analysis of the modern science of criminology by one of its distinguished founders. The development of Lombroso's theories, from his early student days, when he wrote an appreciative critical review of a work which endeavored by means of comparative philology to explain the origin of the earliest religions and legal institutions, to his declining years, when he wrote his last volume, which was published after his death, namely, "Researches on the Phenomena of Hypnotism and Spiritism," this development is followed step by step. The author presents a lucid exposition of the principles of criminal anthropology; summarizes Lombroso's views on woman as criminal, on the political criminal, and on criminal psychology; describes Lombroso's life-work as a social reformer, his methods, and his philosophy; and discusses his views on criminal jurisprudence, pellagra, agrarian reform, environment, and the nature of genius. To the physician, the psychologist, the lawyer, and the social worker this book cannot fail to be of interest and profit.

Malaria, its Prevention and Control. By Graham E. Henson, E. Van Hood and E. W. Warren, Special Committee of the Florida Medical Association for the Control and Prevention of Malaria. Jacksonville: State Board of Health of Florida, 1911.

This excellent pamphlet, dealing with a subject of vital importance to the people of the State in which it is issued, may serve as a model for similar publications in other States, though not necessarily on the same subject. In popular style the various aspects of malaria are discussed in their economic and hygienic bearings. The pamphlet is made up of a series of articles that were published in separate bulletins in the daily press.

Society Reports.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held October 16, 1911.

THE PRESIDENT, DR. REYNOLD WEBB WILCOX, IN THE CHAIR.

The Treatment of Diarrheas in Bottle-Fed Infants.—Dr. ROGER H. DENNETT read this paper (see page 1123.)

Dr. RANSFORD E. VAN GIESON said that after a careful study he had not been convinced that sugar, in normal proportions, is causative of infantile diarrhea, but he believed that in the treatment of this affection we must reduce *all* the constituents of cows' milk to a minimum adapted to the individual case. He had never used cow lactose in his milk modifications. As to the "eiweiss mixture" (which by the way was a misnomer, since it contained no egg albumin), this was a compound of sifted, separated whole milk casein and buttermilk. Many years ago he had reached the conclusion that if cow casein were separated and diluted simply with water and ½ per cent. of gelatin with 10 to 20 per cent. of lime water it would be more easily digested. It was requisite that the milk should be bottom or skim milk. It was coagulated with rennin and well shaken in a capacious bottle. By this method the casein was much more finely separated than by rubbing it through a sieve, and there was less danger of infection. Diluted 2½ volumes it would give 1 per cent. lactose and less than 1 per cent. undissolved casein. The percentage of fat was a very small fraction. For a temporary food this, alternating with 25 per cent. cream diluted to ten volumes, with 20 per cent. lime water, was productive of good results. The great point was the adaptation of this foreign substance—cows' milk—to the weakened digestion of the infant, and the treatment, he believed, was chiefly prophylactic. Dr. Dennett's classification of diarrheas he thought was excellent.

Dr. GEORGE DOW SCOTT said that he was not a little startled when he first heard of this use of boiled milk, as all the teaching for many years was to the effect that boiled milk was indigestible. The results which Dr. Dennett had obtained, however, showed that we must modify our views in regard to the matter. Some of us had been trying all sorts of methods in infant feeding, and had now come down ot the use of the pure raw milk furnished by the milkman, modified with a certain amount of water and with lime water to make the mixture alkaline. Sugar, in proper quantity, acted as a tonic, but too much of it would excite diarrhea. Every mixture should be such as the child would like to take, and it was important to remember that it should contain the three elements, proteid, fat, and carbohydrate. It was a mistake to prepare a milk mixture for twenty-four hours at a time. Every feeding should be freshly made, and the lime water added at the last minute.

Dr. L. W. ZWISOHN said that twenty years ago or more it was recognized as the rule to give boiled milk. In the treatment of infantile diarrhea much depended upon the child itself and its condition, and it was often a question of not so much what to give but how to give it.

Colon Bacillus Infections, with Report of Double Pneumonia and Purulent Bronchitis (Colon Infection) with Recovery.—Dr. ROBERT COLEMAN KEMP reported the case of a male patient, forty-eight years of age, who on March 1, 1910, was operated on in the New York Hospital by Dr. Frank Hartley for a right inguinal hernia. Shortly afterward pyelitis, first of the left kidney and then of the right, developed, and on March 14, when a small pneumonic area was discovered at the base of the right lung, Dr. Kemp was asked to take charge of the case. On March 16 there was a sudden attack of heart failure, with fall of temperature, which very nearly proved fatal. After that there was gradual improvement until midnight, March 24, when the patient was taken with an extremely severe chill, which lasted half an hour. The temperature shot up to 104°, dropped to normal, and then gradually rose to 102°. As there was no apparent cause for this condition, and as the pyelitis was still in evidence, Dr. Kemp, having known of a number of cases of colon bacillus infection with the same type of chill, suspected the presence of this infection and, without waiting for the examination of the urine for the organism, at once increased the amount of urotropin (which the patient had been taking for the pyelitis) from ten grains three times a day to ten grains every three hours, and added ten grains of sodium benzoate to each dose. In the morning a large number of gram-negative bacilli were reported in the urine. The urotropin and sodium benzoate, in these doses, were continued every three hours, both day and night—a total of 80 grains of each per day; and later pure cultures of colon bacilli were reported in the urine. Resolution of the lung was slow, and the temperature, having declined to 99.5°, remained about this point. There was little expectoration, but abundant colon bacilli were found in the sputum. In early May a sharp attack of colitis occurred. Irrigations of the colon with acetozone and dissolved lactic acid bacilli tablets were then begun and kept up thereafter. Subsequently there was a second attack of pneumonia (this time at the left base), and colon bacilli were again found in the sputum. It was mild in character, though resolution was slow, and it was believed that the saturation of the patient with urotropin was undoubtedly contributory to this mildness. Next came a sudden attack of acute purulent bronchitis. So thick was the pus that a pulmonary abscess was feared, and culture showed enormous numbers of colon bacilli and some streptococci. Autogenous vaccines were then begun. The bronchitis improved, but there was no disappearance of the bacilli from the urine, although the vaccines were given daily by advice of the pathologist. At the end of three weeks these caused marked reaction, and they were therefore stopped. By the end of May the patient's condition was so far improved that he was removed to his home. In June there occurred an exacerbation of the pyelitis and a coincident attack of colitis—a very suggestive circumstance which tended to confirm Dr. Kemp's opinion that the colon bacillus infection was autogenous from the gut. The vaccines were again administered, but as considerable reaction was caused which rather alarmed the patient they were discontinued. Early in July he went to the country. At this time there were evidences of a mild myocarditis, which was believed to be chiefly due to the toxemia. Twice each week the urine was sent to New York for examination, and early in August the colon bacilli disappeared from it. It remained free from them until October. On the first of that month the patient, who was a broker, returned to the Stock Exchange and, against advice, persisted in full days' work. In a few days he began to have chilly feelings, with a slight rise of temperature, and the colon bacilli reappeared in the urine, though not in great numbers. These gradually diminished under treatment. Dr. Wm. H. Thomson, seen in consultation, agreed with Dr. Kemp that further rest was necessary, and the patient accordingly went abroad. On December 24 he wrote that his temperature remained normal, though a few colon bacilli still persisted in the urine. In this case no evidence of renal irritation from the large amount of urotropin taken could at any time be discovered. In January the patient reported that the bacilli had disappeared from his urine. On May 1, 1911, he returned to New York and resumed business. The urine remained free from colon bacilli until some time in July, when he had a sudden attack of tonsillitis, with an immediate re-

turn of the bacilluria. Under rest and the use of the urinary antiseptic the condition gradually improved.

In this paper Dr. Kemp said he desired to call attention to the various conditions which infection by the colon bacillus might produce. In some instances these simulated other diseases, and hence serious errors in diagnosis were liable to result unless we considered the possibility of this type of infection. Doubtless in a large percentage of cases the selective point of infection was in the urinary tract, though infection occurred elsewhere with considerable frequency. Fortunately, in the majority we could determine the source of trouble by the discovery of colon bacilluria, even though there were no urinary symptoms. A temporary bacilluria might occur with slight or no symptoms, but the presence of colon bacilli in the urine was a pathological condition, one which might produce serious results at any moment and which called for immediate treatment. The following were the modes of infection of the urinary tract: Ascending infection, through the urethra; descending through the blood stream; infection by contiguity. In the case of the first the greatest number of instances apparently occurred among females, due probably to the short urethra and its proximity to the vulva and anus. Hematogenous infection Dr. Kemp considered the commonest mode. Most frequently there was a solution of continuity or ulceration in the intestinal tract, and he had seen such infection in typhoid fever, intestinal ulcer, and intestinal catarrh. In this connection he discussed the effects of colon bacilli upon the liver, and stated that bacterial infection might influence, and even determine, the development of hepatic cirrhosis. In treating of the third mode of infection he said that the colon bacillus had a definite relation to certain infections in the gastrointestinal tract. Thus, it had been shown to be a factor in acute appendicitis and it had been found in the fluids of acute peritonitis. It had been responsible for inflammation of the pancreas and gall-bladder, and these bacilli had been found as the nucleus of gallstones and of pancreatic calculi. R. T. Morris believed that it might be responsible for some cases of duodenal ulcer, and A. Charlton, in his reasearches at McGill University, had suggested the possibility that pernicious anemia might at times result from colon bacillus infection. H. G. Harris had reported a case of infantile paralysis in which colon bacilli were found in abundance in the urine. In view of the changes produced experimentally in the spinal cord by the injection of colon bacilli into the circulation, this clinical instance was of unusual interest.

The urine in colon bacilluria, unlike other urines decomposed by the bacteria (giving an alkaline reaction and ammoniacal odor), usually remained strongly acid. In mild cases it might appear quite clear, while in more marked cases there might be varying degrees of turbidity, and often it had an opalescent appearance, with a faint mucous cloud. The symptoms of acute colon bacillus infection of the kidneys were well illustrated in a case seen in consultation with Dr. Robert Ahbe, which Dr. William H. Thomson reported in the Medical Record of May 28, 1910. Charles R. Box, of St. Thomas' Hospital, London, in an article in the *Lancet* had observed that in many cases when the kidneys were involved in typhoid fever, scarlet fever, measles and diphtheria the organism found in the urine was the colon bacillus, and Dr. Kemp himself had seen several cases of acute nephritis in the course of typhoid fever which were due to colon bacillus infection. In one instance the patient, having suffered from many of the complications of typhoid, suddenly on the eighty-fifth day of the disease developed severe chills, with rise of temperature and marked oliguria, while albumin, blood, casts, and numerous colon bacilli were found in the urine. Pulmonary edema quickly set in, and the patient died in a few days. A case occurred in the practice of Dr. A. Seibert during the course of scarlet fever in which the patient, a girl of eleven years, in the sixth week of the disease suffered from nausea and incessant vomiting, universal edema, uremic convulsions, and total blindness, with some cystitis and marked oliguria.

Dr. William H. Thomson said he had been struck by the fact that so many well-known medical men were still unaware of the importance of these colon bacillus infections. Not long since he had been called by a prominent surgeon to see in consultation a patient with a pelvic hematoma who had had a sudden attack characterized by high temperature (104°), delirium, and twitching of the face. Dr. Thomson at once asked to see the urine, and it was found to present an appearance which was perfectly characteristic of this type of infection, namely, a peculiar white haziness. When he told him that without doubt the kidneys had become infected by the colon bacillus, the surgeon was taken aback, as he had never so much as heard of such an occurrence. The laboratory examination of the urine showed the presence of the organism in great numbers, and appropriate treatment, with ten grains each of urotropin and sodium benzoate every three hours, was commenced. It was well known that urotropin, when given alone, was apt now and then to cause more or less irritation of the urinary passages. When, however, it was given in combination with the sodium benzoate he had never known it to produce any such effect, and in many instances he had continued its use for months at a time. When, in typhoid fever, the patient, who up to that time might have been doing well, was taken in the third or fourth week with a violent chill, this could in every instance be ascribed to colon bacillus infection. The same thing was true when in cases of chronic nephritis there suddenly appeared oliguria with suppression; a condition which would prove fatal unless treatment were immediately begun. Attacks of this kind were always preceded by an attack of some acute infection of the intestinal tract, such as cholera morbus, and hence, as Dr. Kemp had mentioned, he always dreaded cholera morbus in elderly persons. In these cases, in which the kidneys were completely stuffed with the colon bacilli, the temperature rose very high. In a case which he had seen in consultation with Dr. Brewer it was 106°, and the patient was comatose. Death resulted, and the post-mortem exmaination showed that the kidneys were riddled with collections of the bacilli in pure culture. All persons suffering from nephritis, he thought, should be warned that if at any time they were attacked with some acute trouble they should at once have their urine examined for the presence of this organism. Dr. Thomson had also met with cases of fever apparently of malarial character, but in which the administration of quinine was attended with no benefit. These were really instances of colon bacillus infection. Enuresis in children was frequently due to this cause, and this was especially the case in girls. The same was true in regard to chronic inflammation of the adnexa of the uterus, and every case of supposed pernicious anemia ought to be examined for the colon bacillus. This infection might produce a condition similar to pernicious anemia, but not identical with it. Finally, it might be set down as a rule that nine cases out of ten of cholecystitis were due to this cause. Here the condition was most commonly preceded by chronic constipation.

Dr. Harlow Brooks expressed the opinion that the general lack of appreciation of the grave results of colon bacillus infection lay largely at the door of the bacteriologist. In the books this bacillus was commonly classified among the non-pathogenic organisms. It was true that it might be non-pathogenic, but it was now coming to be recognized that this was certainly by no means always or even generally the case. He did not think that the colon bacillus could invariably be found in the urine, even in

cases of long-standing colon infection. The pyelitis due to this infection was more commonly met with in children, and he had seen a considerable number of such instances. Here the condition was not usually so severe as in some other forms of pyelitis. It was not so strictly inflammatory as that due to the streptococcus or pneumococcus, and was more toxic in character. Indeed, these characters more or less typified all colon infections. As to the treatment, at first he had been sceptical as to the value of the remedies advocated by Dr. Thomson; but after he had seen patients who he thought were going to die recover under these remedies he could no longer doubt. Since then he had personally employed this method of treatment to a considerable extent, and with very satisfactory results. He still believed, however, that where the infection was localized the use of autogenous vaccines was preferable.

Dr. Robert T. Morris contrasted the effects of certain microbic infections on some kinds of animals, such as hares and lemmings, among which the entire family was sometimes nearly wiped out, with those upon the human race, in whom, owing to more elaborate defense organs, the results were less disastrous. Until recently it had been held that the tubercle bacillus group was responsible for more deaths than any other cause. He would not be surprised, he said, if in a short time we should be informed that the colon bacillus group came next to that group in fatality. Its work was certainly very insidious. Dr. Brooks had told us that the bacteriologists had not for the most part made reports on this subject. In medicine we could find everything that we looked for. We had not found the colon bacillus often enough because this required a special investigation to detect, and such investigation had not been systematically made. In a case of nocturnal enuresis in a girl of fourteen to which he was called in consultation he found the urinary report negative as regards the colon bacillus. Ascertaining that this had not been specially looked for, he requested that such a special examination be made, and the result was that colon bacilli were found in great abundance. Under the treatment described by Dr. Thomson the patient, with whom all other measures failed, was now steadily improving. Many of the cases in which the clinical diagnosis of tuberculosis of the bladder was now made he thought might really be due to colon bacillus infection. In the attic of the abdomen certain hieroglyphics were found which showed that toxic influences were very frequent in this region. The adhesions met with there demanded an explanation, and he was now engaged in making an investigation into the matter. Working with him, Dr. B. B. Stroud had found some bacteria resembling the colon bacillus, but whether we had to do with the colon bacillus group or with toxins of this group it was impossible to say at present in connection with these cobwebs of the abdominal attic. As to duodenal ulcer, Dr. Morris believed that in a great many instances of this and of pyloric ulcer a direct toxic infection stood in a causative relation, and that the toxins of the colon bacillus are locally excreted at these points. Such toxins might act in two ways. First, they might cause a spasm of the sheaths of the terminal arteries which, by interfering with the blood supply, brought about a localized anemia and exposed the part to digestive processes and also to bacterial processes. Second, they occasioned a toxic proliferating endarteritis which occluded branches of the terminal arteries. In this way an area corresponding to the distribution of any one terminal artery was rendered vulnerable.

Dr. H. A. Haubold said the colon bacillus appeared to migrate from the gastrointestinal tract, its usual habitat, to various other parts, where it set up an inflammatory action, and the real origin of the local trouble no doubt frequently escaped notice. Personally, he believed that this organism was a very common causative factor. From the surgeon's standpoint it was a very difficult matter to sterilize the gastrointestinal canal. As a preliminary step to operative procedure it was desirable to reduce its flora as much as possible by dilution, sedimentation, and exhaustion, and something could be accomplished in this direction by giving the patient for forty-eight hours before the operation a sterile diet and one which called for hypersecretion of the digestive fluids.

Dr. E. M. Alger said that as regards choroiditis Dr. Gould had reported a historic case, and at least one other similar case had been published. We all knew that this affection might result from infection, and it was now evident that the colon bacillus might be a causative factor.

The president, Dr. Wilcox, said it was remarkable, after the bacteriologists had told us for so many years that the colon bacillus was non-pathogenic, that in a comparatively short time it was discovered that it was responsible for so many serious ills as were set forth in Dr. Kemp's exhaustive paper, and it was also very remarkable that so soon after this discovery we should be in possession of a remedy such as that for which we were indebted to Dr. Thomson.

Dr. Kemp, in closing, said that he had been misunderstood on one point by Dr. Brooks. In the paper he had not stated that the colon bacillus could be found in the urine of all infected patients, but that this was the case "in a large percentage of cases." That the remedy employed was free from injurious effects seemed to be pretty clearly shown in the case reported, where 80 grains a day were taken continuously from March 1 until August without any untoward results. Several cases were on record in which 120 grains a day were given, and one in which no less than 240 grains in the twenty-four hours. In this latter instance some irritation was produced, as shown by the appearance of albumin, casts, and blood in the urine, but it subsided when the drug was temporarily suspended. After it was resumed there was no further trouble, and the patient went on to recovery.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirty-seventh Annual Meeting, Held at Nashville, Tenn., October 17, 18, and 19, 1911.

The President, Dr. Robert H. Babcock of Chicago, in the Chair.

(*Continued from page* 1098.)

The General Management of Tuberculosis. — Dr. Thomas D. Coleman of Augusta, Ga., stated it was scientifically susceptible of proof that this disease could be stamped out in a few generations. If every human being capable of spreading tuberculosis could be kept in a sanatorium until he was incapable of spreading the disease, it would not be long before it would be as infrequent as cholera, yellow fever, and smallpox. Wealth, social influence, ignorance, and lack of sufficient sanatoria made this for the present impossible, so that the great weight of the problem must for many years rest on the shoulders of the general practitioner, and his work was that not only of curing the sick, but educating the sound. Under proper medical direction, when a reasonable hygienic régime could be procured, he believed results little if any short of those obtained in sanatoria could be secured. These could be gained through education of the public and intelligent medical oversight. The earlier the diagnosis the greater the promise of cure, for no one acquainted with the problem doubted the curability of tuberculosis in its earlier stages. That an antitoxin of the nature desired and needed would be discovered he had not the slightest doubt. As no tuberculin, whatever the name, had been discovered to improve

upon or even equal the results of Koch's, he would content himself with summarizing what might be expected by its employment: 1. In diagnosis in human beings it had been found efficient in from 60 to 75 per cent. of cases; in cattle from 95 to 97 per cent. In the treatment of certain incipient and quiescent cases in human beings, in the hands of experienced observers, it had produced beneficial results. 3. Its use was contraindicated in cases of active tuberculosis and in far advanced cases. 4. Its untoward effects in certain cases made it inexpedient to recommend it as a routine treatment to the general practitioner. We were, therefore, left in the treatment of this disease to the sum total of the experience of the ages in its management. From this we gathered encouragement from two indisputable facts, even in the absence of a specific cure. These were that without further discovery we could by prophylaxis and our own methods of treating the disease make it as infrequent as smallpox, yellow fever, or other like pests. The sanatorium treatment was in the main the ideal treatment, but individual advantage, the large number of tuberculous patients, and the relatively small number of sanatoria made the problem one which the general practitioner must solve, and the responsibility was in a large measure his. Tuberculosis in its early stages was a curable disease; when far advanced it was incurable. Its early diagnosis was therefore most desirable. In all cases four requisites were necessary, namely, fresh air, food, rest, or directed exercise and intelligent direction. Climate had its effect on the production and course of the disease. No climate cured all cases, but some climates were beneficial to most cases; some were prejudicial. In any climate fresh air had a more favorable influence than bad air. A bad climate with fresh air was better than a good climate with bad air. It followed that it was better for a patient to stay in a bad climate where he had pure air rather than to go to a good climate where he had bad air. Naturally this problem of pure air was encountered in his housing. He was a firm believer in the beneficial influence of climate. Every tuberculous patient should have all the sunlight possible.

Hemorrhage in Typhoid Fever.—Dr. Walter F. Boggess of Louisville stated that for the past fifteen years it had been his habit to give every patient with typhoid fever five grains of salol, ten grains of urotropin, twenty grains each of subnitrate and subgallate of bismuth in suspension every four to eight hours. In a condition of intense catarrh from the tip of the tongue to the colon with ulceration, with or without constipation, it appeared to him that the bismuth salts were indicated. The urotropin and salol being intestinal, genitourinary, and systemic in their antiseptic properties, could be given with good effect. These were a dose of castor oil every three or four hours, and normal saline enemata each day, whether or not diarrhea was present, were given. In 223 cases of typhoid fever thus handled not a single one of them showed any hemorrhage. The three severe hemorrhages that he had mentioned occurred in ambulatory patients, and his first visit was during the hemorrhage. He felt sure that this treatment was prophylactic and curative. As to the treatment of the hemorrhage itself, at first glance the indications were threefold: first, to put the bowel at rest by lessening peristalsis; second, to increase the coagulability of the blood, either local or systemic, or both; and, third to sustain the patient; the after-treatment was also a matter of some importance. Prophylaxis was a matter of great importance as obtained by the proper handling and treatment of the case, and hemorrhage, when it did occur, while alarming, was not a symptom *per se* of gravity, and each individual case was a study unto itself, and the physician who used good sense, applying his remedies physiologically and scientifically, had a bulwark, a means of defense, security, and safety, that would ordinarily carry him safely to a successful end.

Dr. George Dock of St. Louis said that the first thing to do in such cases was to give the patient enough morphia to quiet him, because he had hardly seen one who did not need quieting. When to move the bowels was an important point, and he had come to solve this in rather an empirical way. As long as the patient was comfortable, he waited often three or four days, but if the patient showed the slightest discomfort in the lower bowel he did not hesitate to give him an enema, either a saline solution, or even a soap suds enema containing castor oil. He thought this was better even though it would start a little hemorrhage.

Hygienic and Dietetic Treatment of Arterial Tension.—Dr. Arthur R. Elliott of Chicago said that we must not lose sight of the fact that high blood pressure was a symptom, not a disease. In the present state of knowledge hypertension appeared to be due to toxemia, certain secondary organic changes, arterial fibrosis, and cardiac hypertrophy, following from overfunctioning of the cardiovascular apparatus produced by the circulatory toxins. The existence of arterial hypertension was not necessarily an indication for treatment. It was difficult often to decide whether we should attempt to lower blood pressure at all in any given case. A blood pressure of 200 mm. or higher might be essential to the maintenance of circulatory efficiency. This was true of most cases of chronic nephritis. Again, the symptoms ordinarily attributed to high blood pressure might be more dependent on disturbance of heart function than on elevated blood pressure *per se*. Even in matters of diet and hygiene we might by over-strictness impair the patient's strength and reduce his circulatory efficiency. This symptom was met with alike among the rich and poor, the thin and the fat. Owing to variation in type and circumstances it was difficult to lay down any absolute rules to govern diet and hygiene that would be appropriate for any major group of cases. Preliminary investigation should be directed to put the patient in as good general condition as possible, and especially to eliminate toxic factors. Tobacco should be interdicted in severe cases and cases with bad hearts, and strictly controlled in all. Exercise and activities should be regulated on the physiological level, using methods suggested by the work of Gräupner and Lowsley to estimate the individual capacity for exertion so as to keep within the physiological limit and so avoid overstrain to the heart and brain circulation. Such rest should be enforced and periodical "bed weeks" advised in cases with weak hearts. The diet should be individualized according to age, activity, and the state of the heart. Corpulent individuals should be reduced, and thin patients gain somewhat in weight. Reduction in total bulk of food was desirable in the former types. Limitation of protein within the physiological ratio of 90 gms. should be enforced in all cases, and in severe cases, especially when renal in type. The quota of protein should fall to fifty grams, or even lower. Hypertension waves or crises should be combated by rest, starvation, or a low diet of milk and cereals, or bread and fruit with limitation of fluids. Fluids should be restricted in ratio to the amount of urine secreted. The greatest parsimony was practised in cases with small urinary flow. Salt restriction was advisable in all cases, and salt withdrawal in every case showing edema, however slight. As these patients were very nervous and impressionable, they should be habitually encouraged and should not be informed of the fluctuations in their blood pressure.

Dr. Alfred C. Croftan of Chicago said an important point in Dr. Elliott's paper was that every case of arterial hypertension did not necessarily call for regulation. This was simply a broad rule which applied to almost every morbid phenomenon. It might call for regulation, or it might call for encouragement. A symptom of that kind might be one of the means of defense against disease. As to diet, he had been inclined to the mechanical rather than the chemical side. He tried to give these patients a diet which did not distend the stomach and colon unduly with

solids, liquids or gas. The diastolic action of the heart was always impaired in these cases, and anything that pressed upward on the diaphragm was not good. Hydrotherapy, Dr. Croftan said, was a therapeutic measure of the very greatest importance in the treatment of cases of arterial hypertension.

Dr. Robert B. Preble of Chicago said the successful handling of these cases required, first, that our knowledge must be more complete than it was now, so that we might be able to direct our patients intelligently. Second, our patients must be sufficiently intelligent to carry out the directions which we gave them. Third, the very practical difficulty which we frequently encountered was a question of dollars and cents. These conditions were extremely common among the poor, and Dr. Preble said it was utterly useless to talk to the average poor patient about the unattainable things one would like to have him do that would be for his good.

Dr. Fenton B. Turck of Chicago said we were ignorant of the etiology of this condition, but in the last ten years a great deal of experimental work had been done, and we were advancing and were using methods that were giving us a good basis for continuing along lines never before followed.

Dr. Albert E. Sterne of Indianapolis said there were two classes of these cases: one in which there were manifested organic conditions which had to be dealt with—cardiovascular, renal, or hepatic. But where there seemed to be a manifest discrepancy between the peripheral tension and the central heart force we were dealing largely with that mysterious system, the sympathetic nervous system. In some instances these cases would react to the simple mechanical treatment, but in those in which there were manifest cardiovascular changes and commensurately strong central action systematic venesection was one of the best remedies he had had at his disposal. It was true that after a comparatively shorter or longer lapse of time the rise in peripheral tension recurred, but when the procedure was systematically carried out, Dr. Sterne said he had found venesection in selected cases a valuable therapeutic agent.

The Treatment of Cerebral Hemorrhage.—Dr. E. M. Hummell of New Orleans emphasized the necessity of taking into consideration the conditions that conduce to cerebral hemorrhage, namely, renal, circulatory, and arterial disease. The most important of these was the blood pressure. In the light of recent research the most active agents in raising and maintaining high blood pressure were the derivatives of tyrosin. Hence the great necessity for avoiding foods which contained these substances in excess. Chief among these were meat, eggs, and milk. The treatment of the immediate and remote results of apoplexy was passed over rather cursorily, but certain important points were dwelt upon, such as the necessity for making a distinct diagnosis of the presence or absence of syphilis, which must be done by cytological examination of the spinal fluid instead of by the Wassermann test. Reference was made to the sensory symptoms, and emotional disturbances provoked by hemorrhage in the optic thalamus. The value of iodide of potassium in nonsyphilitic cases of arterial disease was questionable, Dr. Hummell said, and preference was given to the alkaline treatment recommended by Lauder Brunton.

Digitalis.—Dr. Frederic Tice of Chicago reviewed briefly the physiological action of digitalis. It was quite generally agreed that digitalis was a cardiovascular tonic, but just how it produced its results opinions were divided. Some believed that its action was neurogenic, others that it was myogenic, while some maintained that it acted by both nerves and muscles. At present, in view of the recent progress in the anatomy and physiology of the heart, the myogenic theory was most acceptable. According to Gaskell, the heart muscle possessed the functions of rhythmicity, excitability, contractility, conductivity, and tonicity. Cushny stated that the influence of digitalis on the vagus produced not only a slowing, but also reduced the strength of the contraction, the conductivity, and the tone of the myocardium, while the direct effect on the muscle increased the strength of contraction, the excitability, and the tone; but the effect on conduction had not been definitely determined. The arterioles were contracted by direct effect on the muscular walls. Therefore, when digitalis was administered it affected both the heart and arterioles; the heart was slowed and the beats were strengthened, while the arterioles were contracted. The effect on the hart was beneficial in several ways. The slowing of the heart prolonged diastole, permitting more rest, more opportunity for repair, and greater accumulation of energy for the oncoming beats. The increase of force not only emptied the heart more completely, thus better filling the arteries, but the increased suction action during diastole assisted the onward flow by withdrawing the blood from the overdistnded veins. So far as the left heart was concerned, the slowing and increased force of contraction, producing a more complete emptying and better filling, would be of service but for the incompetent valves. At the same time the peripheral resistance was increased, so no advantage was gained. On the right heart, however, the results were much different. As there was no influence by digitalis upon the pulmonary arterioles, the whole effect was exerted upon the right auricle and ventricle, which were more completely emptied and better filled. In mitral stenosis digitalis might or might not be beneficial, for the conditions were not so favorable. The literature contained considerable on the use of digitalis in aortic insufficiency. When the failure was manifest by mitral insufficiency and a venous stasis, the same favorable conditions were present as in a primary mitral insufficiency and digitalis would be of assistance. The ideal preparation was one representing the active principle of digitalis in definite strength, one that was suitable for hypodermic or oral administration and devoid of the disturbing effects either locally or upon the gastrointestinal canal. The intravenous method was to be preferred as no pain or reaction was produced and the effects were prompt. It was by this method that digalen was of the greatest service. Under ordinary circumstances, where digitalis was indicated, 1 c.c. in twenty-four hours was sufficient, but the amount and the frequency, one or both, might be increased as occasion arose, to meet the demand in any individual case. The same vein might be employed repeatedly without the least discomfort so long as the digalen was injected into and not about the vessel.

The Rôle and Methods of Psychotherapy in the Care of Psychasthenia Tending Toward Inebriety.—Dr. Tom A. Williams of Washington, D. C., read this paper (see page 919).

Dr. Curran Pope of Louisville said that in the practical treatment of these cases they naturally presented the two sides the essayist mentioned, namely, the physical and the psychasthenic side, and it seemed to him that where a physician regarded either side alone he made a mistake. The physical demanded just as much attention as the psychasthenic, and the man who bore this in mind was more apt to reach a truer solution of the case than he who did not. In these cases great benefit arose from rational treatment, such as diet, exercise, etc., but he did believe that no cases were really ever cured until physicians found by psychological analysis the various underlying factors of the mentality of the patient upon which these conditions were built. As soon as these tenets were established one would benefit the patients, or would cure the patients.

(To be continued.)

MEDICAL ASSOCIATION OF THE SOUTHWEST.

Sixth Annual Meeting, Held at Oklahoma City, Okla., October 10 and 11, 1911.

THE PRESIDENT, DR. M. L. PERRY OF PARSONS, KAN., IN THE CHAIR.

(*Concluded from page 953.*)

Chronic Colonic Intoxication.—Dr. JOHN F. BINNIE of Kansas City, Mo., drew the following conclusions: 1. Chronic intestinal stasis was exceedingly common. It gave rise to diverse and obscure symptoms, and was at least one cause of neurasthenia. 2. It might be due to various causes, but the real etiology was yet unknown. 3. Failure to obtain relief from symptoms of appendicitis after appendectomy was often due to the fact that appendicitis, if present at all, was merely an accident in the course of a case of chronic intestinal stasis. 4. In every operation for chronic appendicitis the surgeon ought to examine the whole cecum and the terminal segment of the ileum.

Dr. H. C. CROWELL of Kansas City, Mo., said there were some forms of intestinal stasis that were doubtless benefited by attention to diet and different forms of medication, but a large number of patients suffered from chronic autointoxication and neurasthenia, on account of adhesions or interference with the peristalsis of the gastrointestinal tract, and it was the duty of every surgeon who opened the abdomen to make a careful examination in every case, not only for pelvic lesions and lesions which he was going to attack, but he should make a general survey to see if there did not exist adhesions which might interfere with peristalsis. He had seen several cases of pericolitis since his attention had been directed to it by Dr. Jackson, and he was able to make a diagnosis from his description before operating and to find the membrane. He believed this membrane was congenital, as it did not bear out the conditions, pathologically or histologically, of an inflammatory product.

Dr. A. L. BLESH of Oklahoma City said he did not believe we were dealing with a single pathological condition, but with many. He was called to see a young man in this city who was said to have appendicitis, and in the family at the time there was a case of typhoid fever. In examining this patient and taking the history he found he had had several such attacks as he was then suffering from. These attacks consisted in pain, more or less marked, without marked radiating tendencies, in the right iliac region, at the region near McBurney's point, but he was not able exactly to define the exact point of the pain. The man's condition at the time he examined him was one of profound toxemia. He was fearful he would have an attack of typhoid fever, and that the soreness in the right side was due to a typhoid perforation at the lower end of the ileum. Since there was no danger from waiting, he suggested to the family physician that they wait a week or ten days so as to eliminate typhoid fever. They waited and the condition cleared up. These cases were peculiar in that they did not have a febrile reaction. In other words, they were toxemic.

Dr. JOHN G. SHELDON of Kansas City, Mo., said that these patients should be carefully prepared, for whenever one operated upon the large intestine, whether he did a resection or an anastomosis, he felt he was doing something out of the ordinary.

Surgical Incisions.—Dr. JOHN G. SHELDON of Kansas City, Mo., said that with every surgical incision there were certain points in the anatomy of the skin that should be considered. The importance and significance of muscle in making surgical incisions depended entirely on the part involved and the ability to overcome postoperative tension in the muscles or aponeuroses in question. Muscles united firmly and surely, but their division should be avoided when possible, for tension or suppuration, or both, might prevent a firm union. The incisions of Kocher, Mayo-Robson, and Bevan gave good exposure to the biliary apparatus, not because they were anatomically designed, but because they destroyed the overlying structures as was done in post-mortem work. The long axis of the operative field in surgery of the biliary apparatus extended from the ninth costal cartilage downward and toward the median line, parallel to the fibers of the external oblique, and the fibers of the internal oblique and transversalis were almost parallel to the incision. Such an incision, beginning at the ninth costal cartilage and made parallel to the fibers of the external oblique and separating the aponeurosis of the internal oblique and transversalis, would preserve everything in this region involved except the fibers of the rectus muscle and would give good exposure of the parts, as it was parallel to the long axis of the operative field. He had used such an incision for four years. It had proved so satisfactory that he had no intention of returning to the old incisions and felt that this incision had sufficient merit to call attention to it.

Dr. H. C. CROWELL of Kansas City, Mo., stated that if this incision did the work it would be an improvement over the old incisions that surgeons had been using. He had had more or less trouble in closing some of his incisions, and he would like to see the incision recommended put into practice.

Dr. HOWARD HILL of Kansas City, Mo., said the closure of a vertical incision was the hardest part, but with the incision recommended by Dr. Sheldon it was easy because tension was not great.

Pellagra.—Dr. R. M. GRIMM, Assistant Surgeon, United States Public Health and Marine-Hospital Service, delivered an address on this subject, in which he reviewed the history and treatment of this disease. His remarks were illustrated by numerous stereopticon slides.

Trifacial Reflexes.—Dr. A. H. ANDREWS of Chicago followed with an address on this subject.

Significance of Pain in the Upper Abdomen.—Dr. ARTHUR W. MCARTHUR of Kansas City, Mo., emphasized the point that he attached no importance to a diagnosis of hysteria in conditions in which there was pain in the upper abdominal region, and that it was his firm conviction that there was always a definite underlying pathology connected with these cases. The present generation of physicians might not live to see the day, but he believed it would come when exploratory incisions and a diagnosis of hysteria to account for pain would be unknown.

Abdominal Drainage.—Dr. CHARLES BLICKENSDERFER of Shawnee, Okla., said that in the ordinary cases he preferred the small cigarette drain made by rolling gauze into gutta percha tissue and thoroughly moistened in physiological salt solution. The length was to be governed by the length of the drainage tract to be established. In thick, fat abdominal walls a short drain of this character extending from the muscular fascia to the surface for a period of twelve hours would prevent mural abscess. Where pus was to be drained, a soft tube of proper caliber might be wrapped with gauze and enveloped in rubber tissue. It was sometimes wise to have a strand of straight gauze lying within the central tube. This could be removed and replaced by others when necessary. The surgeon should not drain if it was possible to avoid doing so. He should not use dry gauze for drainage. He should not tuck or fold back and forth gauze to be used as a drain. Gauze packs were useful to control hemorrhage, but often acted as plugs where drainage was sought. One should not use a long drain if a shorter one would suffice. The drain should be removed as soon as its service had been performed, remembering that in pus cases drains were useful for a much longer time than in relatively clean cases.

Dr. JOHN G. SHELDON said there were people who were primarily neurasthenic. They were born with a deficiency

in gray matter; they were sick all their lives and were apt to complain of pain in the abdomen. There were other cases that were secondarily neurasthenic, on account of some pathological condition which resulted in autointoxication or some continued nerve irritation. He believed that some of these cases were surgical and the surgeon should try to find out what was the matter and remove the pathology before the changes in the nervous system had become permanent.

Dr. JOHN F. BINNIE said, with regard to the paper on darinage, that, instead of the familiar cigarette drain, it was a good plan to take some strands of ordinary wool, such as is used in making thick socks, sterilize it, and use it with a hard rubber tube, and it would be found better than gauze.

Dr. J. W. JOLLY of Oklahoma City stated that in all wounds, if the surgeon had an idea that infection had taken place, the proper thing was to drain. He had closed wounds, not having any extra trouble at the time, but had to reopen them, which was unsatisfactory. As to pain in the upper abdomen, he felt sure patients frequently had these pains without the surgeon being able to find any pathological condition to account for them. He had operated for what he supposed was some inflammatory condition, but was unable to find anything abnormal.

Dr. J. D. GRIFFITH of Kansas City, Mo., said with regard to drainage that if he wanted rapid exosmosis he used sterile vaseline mixed with normal salt solution. This, being of greater specific gravity than the exudate that was to come out, would produce exosmosis in the capillary attraction. He had been using it for some time and it cut drainage short and gave him an abundance of drainage. If one put one-quarter sterile vaseline on the gauze he would find the exudate would be increased very materially.

Dr. S. H. MAYBERRY of Enid, Okla., thought future investigation would show that the greatest amount of pain in the abdomen would come from an inflammatory condition of the parietal peritoneum or from some tension on the mesentery, and not the intestine, the stomach, the gall-bladder, and appendix. By bearing this in mind he had been enabled to make a diagnosis where before he had failed.

Dr. MCARTHUR, in closing, stated that abdominal pain always meant some definite pathology; that this might be medical or surgical pathology.

Dr. BLICKENSDERFER, in closing, said the necessity for drainage depended largely on the man who operated. If the surgeon was quick in operating, as a rule no drainage was required, but if the operator was slow in the vast majojrity of cases drainage would be required.

Dr. L. H. HUFFMAN of Hobart, Okla., presented a comparative study of the practice of surgery in Mexico and the United States.

Septic Infection.—Dr. W. J. JOLLY of Oklahoma City stated that in puerperal septicemia we were helpless so far as specific treatment was concerned. The local treatment usually used, curettage, was harmful and only opened up new avenues for the absorption of toxins and aggravated the condition rather than benefited it. It was only justifiable in cases where there was known to be retained placenta. While it was the ideal treatment in sapremia caused by a blood clot or retained placenta, it was to be condemned in true septicemia. The use of the sera he believed to be worthless after a thorough trial of them. He knew a few cases got well under any kind of treatment, but in his own experience they did not modify the disease in the least. The only treatment for general septicemia was supportive, easily digested, nourishing food, and stimulants to sustain the patient until Nature manufactured antibactericidal serums or opsonins to destroy the bacteria. Urotropin was used internally with the object of carrying an antiseptic into the blood and destroying the bacteria. Theoretically it was a good treatment, but practically it was a question of getting enough of the drug into the circulation to accomplish a great amount of good.

Dr. S. M. MAYBERRY said he believed in the use of the curette in removing portions of retained placenta, and he thought there were times when this instrument, if not properly used, would necessarily carry infection into the healthy muscular coat and do harm. When it came to washing fresh wounds, after removing all foreign material he favored the use of tincture of iodine and the application of a hot, moist boracic acid and alcohol dressing, using 95 per cent. alcohol.

DR. JOHN F. BINNIE said that many years ago a Berlin surgeon made some investigations as to the sterilization of wounds, and unfortunately in the laboratory found that when bacteria had been in contact with a wound for so many seconds or minutes there was no use in trying to do anything. The bacteria were absorbed according to the laboratory experiments. This would have brought about to a large extent therapeutic nihilism if there had not been found "a nigger in the woodpile" as regards these experiments. More recently Frederic, carrying on similar experiments, found that bacteria in a freshly made wound might be reached by aseptic or antiseptic means for a period of six or seven hours after the wound had been infected. Methods of treatment of fresh wounds had changed in the last few years.

DR. JOLLY, in closing, said that where it was known that there was retained placenta in the uterus he would advocate removing it, but in true septicemia the bacteria had left the surface and had gained entrance to the circulation, and curettage would do no good whatever in such cases, and would produce more or less traumatism even with a dull instrument. He believed the use of the curette in the majority of such cases did harm.

Cancer and Its Treatment.—Dr. W. L. KENDALL of Enid, Okla., said, regarding the treatment of this disease, that the remedies that had been proposed for its cure were legion, and the result of every investigation had convinced him that the only cure was in the hands of the surgeon. The field of usefulness of the various nonoperative procedures had steadily narrowed down to the inoperable and irremovable cancer. The *x*-ray was absolutely valueless in deep-seated cancer, and its field of usefulness was limited to a few varieties of superficial epithelioma and lupus. Radium was of no more value than the *x*-ray, and should never be employed where the case was amenable to the surgeon's knife.

Dr. H. C. CROWELL of Kansas City stated that, according to the latest statistics, 100,000 people died annually of cancer. Three-fourths of this number were cases of cancer of the uterus, due largely to the fact that the patients were seen late by the surgeon. People should be educated to the necessity of early recognition of this disease. A woman with the manifestation of leucorrhea, purulent discharges, and the appearance of blood from the uterus should consult a doctor early. Good results were obtained by operating on some of these cases early.

DR. BACON SAUNDERS stated that there was a time in the history of every cancer when it was curable, and this should be kept before the eyes of both the public and the profession.

Dr. DAVID A. MYERS of Lawton, Okla., said that, if in three-fourths of the cases of uterine cancer the disease was due to laceration of the cervix, why not educate the general practitioner to repair the cervix at the proper time, which was the puerperium. While we could not prevent cancer *per se* by repairing the lacerated cervix, we could prevent the thing which we found in the majority of cases was causing the cancer.

DR. GEORGE B. NORBERRY of Kansas City, Mo., said he

believed every woman with a lacerated cervix would be better off to have it repaired, no matter whether it was causing trouble or not. He had tried the use of the galvanocautery in these cases and it was remarkable the amount of good it did.

Dr. John F. Kuhn of Oklahoma City said that the cautery must not be heated to its greatest intensity, but hot enough so that when it was long enough in contact with the tissues, the deeper structures were robbed of their vitality by its heat. It was a mistake to use the cautery so hot that it would sear the superficial surfaces and not cauterize the deeper structures.

Dr. J. D. Griffith of Kansas City said that the cautery should be heated to a cherry-red, then it would do its work.

Dr. H. C. Crowell said that in the advanced cases of cancer it was a question whether to resort to hysterectomy or to cauterization with the hot iron, chlorid of zinc, or with acetone.

Dr. Griffith stated that in the advanced inoperable cases he had used what was known as the acetone pack and had taught the patients to apply it themselves.

Dr. Norberry asked how these patients guarded against burning the vagina with the use of the acetone pack.

Dr. Griffith replied that the acetone pack would not burn the vagina if it was protected by vaseline.

Operative Treatment of Inguinal Hernia.—Dr. A. C. Scott of Temple, Texas, stated that operative treatment of strangulated hernia differed in many respects from that of deliberate operation for radical cure. First, in the unpreparedness of the patient; second, the amount of trauma produced on attempts at reduction caused discoloration and great edema of the coverings, the sac and its contents; third, if the strangulation was complete, there might exist gangrene of the omentum or gut, perforation and peritonitis, which might render the situation very grave or wellnigh hopeless. The above remarks applied to hernia in general. Since 1902 he had been endeavoring to overcome the weak points in the two most excellent operations of Bassini and Halstead by transplanting the cord high enough to obtain strong muscular fibers to be sutured around the cord, at its point of exit, and by suturing the aponeurosis of the external oblique under the cord in the lower half of the canal, thus closing the external inguinal ring and giving the wall double strength where it needed it most in all the direct and many of the oblique hernias. After describing the technique of the operation, Dr. Scott stated that of the 238 operations made by him he had found but one unsatisfactory feature, namely, that when the aponeurosis was drawn too close around the cord it might impede the return circulation sufficient to cause marked swelling of the testicle. The swelling usually subsided by the time the patient was ready to resume work, but such a result was unnecessary and could be avoided by placing the two sutures which formed the new external ring at a sufficient distance apart to give ample room, or in case the cord appeared to be unduly encroached upon after the sutures were in place, the ring, or more properly speaking, the gap in the aponeurosis, could be widened by snipping its edges with blunt scissors. It was safe to stitch the internal oblique close around the cord, but not so with the external oblique without snipping the margins to widen the aperture which closed somewhat like the blades of a pair of scissors. With due caution in this respect, he could not see much more to be desired in the technic for radical cure.

Total or Subtotal Hysterectomy.—Dr. H. C. Crowell of Kansas City, Mo., said that no operation in his experience had given so much satisfaction as had total hysterectomy, most of his patients recovering speedily, going home in two weeks as a rule. The shock from total hysterectomy was little, if any, more than from amputation, as the loss of blood, if successfully done, was no more. The only difference was it took a little longer. The desirability of total hysterectomy in preference to the subtotal, operation, he felt, must be obvious, as it removed the cervix entirely, which had so often proven a reflection to the subtotal operation. Better drainage and fewer adhesions resulted from total hysterectomy, and finally more uniform results. After a not inconsiderable experience he had no hesitation in urging a more generous consideration of complete hysterectomy with the full confidence that better results would obtain than from amputation.

Do You Do Your Duty in the Obstetrical Chamber?—Dr. David A. Myers of Lawton, Okla., said that a wholesome surgical fear and a good surgical conscience were two very essential things for a physician. He should not let his surgical fear extend to the end that he would not repair a lacerated cervix following childbirth, and he should not let his conscience dig him for not doing so. The technique, when once tried, was very simple, and the results were so good that the procedure should occupy the same place as the immediate repair of the perineum.

High Frequency Current in Chronic Urethral Affections.—Dr. W. T. Wooton of Hot Springs, Ark., related his experience in the use of the high-frequency current in treating 41 cases of chronic gonorrhea, 41 cases of gleet, 31 cases of stricture, 11 cases of prostatitis, 7 cases of urethral hyperesthesia, and 1 case of fibrosis. In favor of the high-frequency current in this work, he felt that he could get rid of the morning drop in 90 per cent. of the cases applying for treatment. Previous to the use of the current treatment was most disappointing, and the drop very persistent. Strictures dilated with less pain and did not contract afterward to the extent that they did when treated by galvanism or the steel sound.

Cerebrospinal Meningitis.—Dr. Wilmer Allison of Fort Worth, Texas, reported a case of this disease. The interesting features were the prolonged course after marked improvement which followed the use of the serum; the violent reaction which followed the last four doses of serum, the internal hydrocephalus, the relief of which was followed immediately by marked improvement, the retained clear mentality throughout the case, and the increased growth of hair over the entire body.

Modern Methods of Diagnosis and Treatment of Syphilis.—Dr. William Frick of Kansas City, Mo., said that the clinical diagnosis of syphilis was most important but generally sufficient, but should be supplemented by laboratory diagnosis in the primary stage or in doubtful cases later on. It was not wise to lay aside the old reliable remedies for the treatment of syphilis just because a powerful new remedy had made its appearance; because the new remedy might be attended with dangers and discomforts which outweighed its advantages.

The Treatment of Pellagra.—Dr. E. H. Martin of Hot Springs, Ark., stated that his conclusions concerning salvarsan were based on close observation of patients receiving 220 doses, either first, or second, or third, or fourth doses. His conclusions and opinions as to the curability of pellagra were based upon the personal treatment of 41 cases, ranging from the mildest to the most severe. 1. Soamin would relieve all of the symptoms of most cases of pellagra. It failed only when the condition of the patient was so feeble, complications so severe, or the disease so aggressive that it could not be given in sufficiently large doses. Usually it caused no reaction unless given in over five-grain doses. Some cases would require more and could not stand the reaction from the endotoxins. Given in ordinary doses it must be kept up for several years; the time yet uncertain. It was probable that if ten-grain doses were safe that there would be no relapse. 2. Salvarsan caused no symptoms if properly given to healthy people. In short, no disease germs, no reaction. 3. The fever following the administration of salvarsan to a case of syphilis was not due to the drug, but to the endotoxins released

from the killed germs, and was both diagnostic and prognostic. 4. The fever following the administration of salvarsan to a case of pellagra was not due to the drug, but to the endotoxins which were released from the killed germs, was also diagnostic and prognostic, and further proved beyond a doubt that pellagra was a parasitic disease caused by a microorganism vulnerable to salvarsan. 5. That it was at least reasonable to believe that this organism was a spirochete or a spirillum. 6. That the character of the reaction, the duration of the fever especially, showed that the germs of pellagra were located principally in the brain and spinal cord. 7. That the endotoxins which were released by the destruction of the pellagra germs were so highly toxic to the human host that the dose of the drug must be proportioned so as not to destroy too many microorganisms at one time, or the results might be disastrous to the patient. Observing patients given large doses of salvarsan one could readily believe that in some cases a condition paralleling the so-called "congestive chill" in malaria might be produced. 8. Salvarsan did not cure pellagra in one dose, owing to the invulnerability of the germs at an early stage of development. 9. Prompt disappearance of symptoms showed that the older germs were killed. 10. That small and increasing doses, repeated within the time required for the development of the germs from the invulnerable stage to just before the stage of reproduction, gave us a rational treatment for pellagra, and should offer as much certainty of a cure as quinine did in malaria when properly given with respect to the seventh day.

Several other papers were read before the sections on surgery, general medicine, and eye, ear, nose and throat.

Officers.—The following officers were elected for the ensuing year: *President,* Dr. A. L. Blesh, Oklahoma City; *Vice-Presidents*—for Arkansas, Dr. T. B. Young, Springdale; for Missouri, Dr. H. S. Crossen, St. Louis; for Texas, Dr. Freeman; for Kansas, Dr. W. S. Lindsay, Topeka; *Secretary-Treasurer,* Dr. F. H. Clark, El Reno.

Hot Springs, Ark., was selected as the place for holding the next meeting.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

TENNESSEE STATE BOARD OF MEDICAL EXAMINERS.

May, 1911.

ANATOMY.

1. Describe the portal system.
2. Name the ductless glands.
3. What cranial nerve has the widest distribution?
4. Give the origin and insertion of the humeral biceps muscle.
5. Mention any one muscle that moves the humerus forward, backward or inward.
6. Describe Hunter's canal; (*a*) what passes through it?
7. Describe the periosteum.
8. What muscles are attached to the tendo Achillis?

PHYSIOLOGY.

1. Give composition and properties of chyle.
2. Give composition of the blood.
3. Describe secretion, properties, and composition of gastric juice.
4. Give the physiological anatomy of the testicles.
5. Describe the physiological anatomy of the tongue.
6. Give the physiological anatomy of the mammary glands.
7. Describe the excretion of urine.
8. Name all the enzymes required to digest bread.

PATHOLOGY.

1. What is stomatitis? Give the pathology of ulcerative stomatitis.
2. Describe any one pathological condition caused by the excessive use of alcohol.
3. Describe the pathological changes which take place in the lung in lobar pneumonia.
4. Give the pathology of parenchymatous goitre.
5. Describe the pathology of the inflammation of any one serous membrane.
6. Describe the pathology of chronic lead poison.
7. Describe the pathology of cerebrospinal meningitis.
8. Describe the pathological condition caused by the bite of a mosquito.

MATERIA MEDICA.

1. Write a prescription for chronic malaria and state how long the patient should take it.
2. Name two medicines which increase the flow of urine. The source and dose of each.
3. What is the source of digitalis and hyoscyamus? What preparation would you use and the dose of each?
4. What is the source of potassium iodide and what is the dose? Name three diseases for which you would give it.
5. Give the source of iodide of lime and iodide of soda and the dose of each.
6. What is sodium sulphate?
7. What is the source of tetanus antitoxin?
8. What is the source of cascara sagrada? What preparation would you use and what would be the dose?

CHEMISTRY.

1. Describe Esbach's albuminometer and give a quantitative test for albumin.
2. Give a chemical test for pus in the urine; (*a*) for blood.
3. What is urea? (*a*) Its estimation? (*b*) Of what significance in nephritis?
4. What are alcohols and how classified?
5. Give chemical formula for iodoform; (*a*) how prepared; (*b*) physiological effects.
6. What is a simple ether? (*a*) compound ether? (*b*) formula for sulphuric ether?
7. What is benzine? (*a*) chemical formula and properties?
8. What is arsenic? (*a*) occurrence? (*b*) preparation? (*c*) properties? (*d*) Reinsch's test for arsenic?

OBSTETRICS.

1. Describe, anatomically, the internal generative organs of the female; (*a*) state the function of each.
2. What are the dangers of traction on the child and on the placenta?
3. What is involution? (*a*) how long a time is usually required for this process? (*b*) What causes may operate to delay or prevent it?
4. Describe the immediate care of the new-born child when from any cause the mother cannot nurse it; (*a*) give rules for artificial feeding.
5. Differentiate eutocia and dystocia. Mention important varieties of the latter and give their management.
6. In a labor otherwise normal but tedious, how soon would it be proper to interfere, and what symptoms would prompt such a course.
7. When does it become proper to perform craniotomy, and how should that operation be performed?
8. Define puerperal phlebitis and give its pathology, symptoms, and treatment.

SURGERY.

1. How would you diagnose a case of complete inguinal hernia from a hydrocele, and describe the radical cure for hydrocele?
2. Describe in full Bassini's method of operation for the radical cure of hernia.
3. Give the nature of treatment of Pott's fracture.
4. Where does senile gangrene most often occur, and what is the usual cause?
5. Give symptoms and treatment of cholelithiasis.
6. Define peritonitis. State three ways in which the peritoneum may be invaded by bacteria.
7. What are the causes and treatment of paraphimosis?
8. Differentiate dislocation of the head of the femur from fracture of the neck, and give main essentials of treatment of each.

PRACTICE.

1. Name the organic diseases of the heart. Define aortic stenosis. Give the physical signs of it.
2. Define lobar pneumonia. Give general symptoms and diagnosis. Give briefly a treatment.
3. What is the pulse? Name some of the varieties of the pulse and their significance.
4. Define acute Bright's disease. What are the most frequent etiological factors which produce this form of kidney disease? Give a treatment.
5. Define leucocytosis. Define leukopenia. Name four

diseases in which the leucocytes are increased in number. Name four diseases in which the leucocytes are normal or diminished.

6. Define diabetes mellitus. Differentiate between diabetes mellitus and diabetes insipidus. Give a diet for diabetes mellitus.

7. Define dropsy. Name four diseases which it accompanies. Given a disease producing it, how would you treat dropsy?

8. Name some of the common forms of tuberculosis. Give a modern treatment for pulmonary tuberculosis.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

Tennessee State Board of Medical Examiners.

May, 1911.

ANATOMY.

1. See Cunningham's "Anatomy" (1909), page 901; or Gray's "Anatomy" (1910), page 754.

2. *The ductless glands* are: Spleen, thyroid, parathyroids, thymus, suprarenals, carotid, coccygeal, pituitary, and pineal.

3. The tenth cranial (pneumogastric) nerve has the widest distribution.

4. Biceps. *Origin:* Apex of coracoid process of scapula, and upper margin of glenoid cavity of scapula. *Insertion:* Back part of tuberosity of radius.

5. Humerus is moved *forward*, by the Biceps; *backward*, by the Triceps; and *inward*, by Teres major.

6. *Hunter's Canal* "extends from the apex of Scarpa's triangle to the opening in the adductor magnus muscle. The anterointernal boundary or roof of Hunter's canal is the sartorius and the aponeurotic expansion from the adductors to the vastus internus. It is bounded externally by the vastus internus. The adductor longus and magnus constitute its floor or the posterointernal boundary. The canal contains the femoral artery, femoral vein, the long saphenous nerve, and the nerve to the vastus internus. (Gray.)

7. See Cunningham's "Anatomy" (1909), page 71; or Gray's "Anatomy" (1910), page 38.

8. The *Tendo Achillis* is the common tendon of the Gastrocnemius and Soleus.

PHYSIOLOGY.

1. Chyle. *Composition:* Water, proteids, fat, cholesterin, lecithin, and inorganic salts.

Properties: Chyle is a clear, colorless or slightly yellow fluid, alkaline in reaction, coagulable; during absorption it becomes creamy, owing to the presence of fat; its specific gravity is about 1006 to 1022.

2. *Physiological composition* of the blood:

1. Plasma.
2. Corpuscles { Colored. Colorless. Blood-plates.

The *plasma* consists of water and solids (proteids, extractives, and inorganic salts). The *red corpuscles* consist of water and solids (hemoglobin, proteids, fat, and inorganic salts). The *white corpuscles* consist of water and solids (proteid, leuconuclein, lecithin, histon, etc.).

3. *Gastric juice* is a thin, colorless fluid; acid in reaction; specific gravity about 1002 to 1010; and containing about 1 per cent. of solids. The daily secretion amounts to 10 or 15 pints. It contains: Water, pepsin, rennin, hydrochloric acid, chlorides (of calcium, sodium, and potassium), and phosphates (of calcium, magnesium, and iron). Its function is to change proteids into proteoses and peptones, and to curdle the casein of milk; it is also slightly antiseptic, and inverts cane sugar into dextrose and levulose.

The pepsin and rennin come from the central cells in the cardiac glands and from the cells of the pyloric glands. In both of these glands the pepsin pre-exists as pepsinogen. The hydrochloric acid is formed by the oxyntic cells. Just how a free acid is formed from the alkaline blood and lymph is not known. It has been suggested that it may occur as follows:

(1) $2Na_2HPO_4 + 3CaCl_2 = Ca_3(PO_4)_2 + 4NaCl + 2HCl$

or (2) $Na_2HPO_4 + H_2O + CO_2 = NaHCO_3 + NaH_2PO_4$;

and then $NaH_2PO_4 + NaCl = Na_2HPO_4 + HCl$.

4. See Cunningham's "Anatomy" (1909), page 1159; or Gray's "Anatomy" (1910), page 1373.

5. See Cunningham's "Anatomy" (1909), page 1000; or Gray's "Anatomy" (1910), page 1219.

6. See Cunningham's "Anatomy" (1909), page 1207; or Gray's "Anatomy" (1910), page 1430.

7. The mechanism of the *secretion of urine by the kidneys* is twofold: (1) By filtration, most, if not all, of the fluid is eliminated, and also inorganic salts; this depends upon blood pressure, and takes place in the glomeruli. (2) By cell activity and selection, in the cells of the convoluted tubules, the urea, and principal solids are eliminated.

8. *Enzymes required to digest bread:* Ptyalin and amylopsin are the main ones; also pepsin, trypsin, and steapsin.

PATHOLOGY.

1. *Stomatitis* is inflammation of the mucous membrane of the mouth. See French's "Practice of Medicine" (1910), page 725; or Osler's "Practice of Medicine" (1909), page 435.

2. Atrophic cirrhosis of the liver. See French's "Practice of Medicine" (1910), page 843; or Osler's "Practice of Medicine" (1909), page 57.

3. See French's "Practice of Medicine" (1910), page 154; or Osler's "Practice of Medicine" (1909), page 170.

4. "Parenchymatous goiter is a variety in which the glandular tissues or acini undergo more or less active hyperplasia. The gland is generally uniformly enlarged, but sometimes presents lobular or nodular elevations. The tissue is ordinarily somewhat elastic, like that of the normal thyroid, but may in other instances be very firm. Occasionally cystic forms occur, and a subvariety is sometimes distinguished by the term *cystic goiter*. Microscopically there may be found merely a uniform hyperplasia of the glandular acini, without any notable change in the structure of the tissue. In other cases the acini are larger and more irregular than in the normal thyroid, suggesting the structure of an adenoma, and the term *struma adenomatosa* is applied. In most instances the acini contain but small quantities of colloid material, as is the case in the normal gland. Sometimes, however, there is abundant production of colloid, and the acini are greatly distended; the term *colloid goiter* may be applied in such instances. In certain cases the walls of the acini are destroyed and the colloid of adjacent acini runs together, forming considerable cysts. In these instances the thyroid consists of numerous cystic excavations. Changes in the interstitial connective tissue of the gland may be comparatively slight, but may in other cases become conspicuous. The capsule of the gland may be thickened, and the stroma may predominate over the glandular elements. The term *fibrous goiter* has been suggested for such cases."—(Stengel's *Pathology*.)

5. See French's "Practice of Medicine" (1910), page 706; or Osler's "Practice of Medicine" (1909), page 654.

6. See French's "Practice of Medicine" (1910), page 991; or Osler's "Practice of Medicine" (1909), page 376.

7. See French's "Practice of Medicine" (1910), page 141; or Osler's "Practice of Medicine" (1909), page 159.

8. See French's "Practice of Medicine" (1910), pages 239 or 270; or Osler's "Practice of Medicine" (1909), pages 15 or 236.

MATERIA MEDICA.

1. *For chronic malaria:*

℞. Quininæ hydrochloridi gr. xlviij.
Ferri pyrophosphatis solubilis gr. xxiv
Arseni trioxidi gr. ss
Oleoresinæ capsici gr vj.
Misce, divide in capsulas no. xxiv.

Signa:—Take one three times a day, after meals.

This should be continued so long as malarial parasites are found in the blood.

2. *Two medicines which increase the flow of urine:* (1) Digitalis; *source*, leaves of digitalis purpurea; *dose*, two drams of the infusion. (2) Caffeine; *source*, seed of coffea arabica; *dose*, citrated caffeine, 2 grains.

3. Digitalis. *Source:* Leaves of digitalis purpurea. *Preparations:* Fluidextract, ♏j; extract, gr. 1/5; infusion, ʒij; tincture, ♏xv.

Hyoscyamus. *Source:* Leaves and tops of hyoscyamus niger. *Preparations:* Fluidextract, ♏iij; extract, gr. j; tincture, ♏xv.

4. Potassium iodide. *Source:* Iodine is dissolved in a hot solution of potassium hydroxide. *Dose*, gr. vijss. May be used in syphilis, pleurisy, and asthma.

5. There is no such preparation as *iodide of lime*.

Iodide of sodium (not soda) is obtained by dissolving iodine in a hot solution of sodium hydroxide. *Dose*, gr. vijss.

6. *Sodium sulphate* is a colorless, transparent solid, with a bitter, salty taste, and no odor. It is sometimes called Glauber's salt.

7. *Tetanus antitoxin* is derived from the coagulated blood of a horse which has been immunized by inoculation with tetanus toxin.

8. Cascara sagrada. *Source:* Bark of rhamnus purshiana. *Preparations:* Extract, dose, gr. iv; fluidextract, dose, ℥xv; aromatic fluidextract, dose, ℥xv.

CHEMISTRY.

1. "*Esbach's albuminometer* is merely a glass tube graduated and lettered, and used for the quantitative determination of albumin. This tube is filled to the letter U with urine, if necessary previously diluted until its specific gravity is 1008 or lower, and a solution of picric acid (picric acid, 10; crystalline citric acid, 20; distilled water, 1000) is added until the level of the liquid has reached the letter R. A rubber stopper is then inserted, the tube is inverted several times to thoroughly mix the urine and test solution and is then set aside for from 24 to 48 hours. The albumin is precipitated and its height, measured by the numerals upon the scale, represents in gms. the amount of albumin present in one liter (1000 c.c.) of the urine." (Greene's *Medical Diagnosis.*)

2. Chemical test for *Pus* in the urine: Acidify the urine with acetic acid, then filter it, and treat the filter with a few drops of freshly prepared tincture of guaiacum; a deep blue color denotes the presence of pus.

Test for Blood: To the urine add a solution of potassium hydroxide to distinct alkaline reaction; heat nearly to boiling (do not boil). A red precipitate is produced.

3. *Urea* is the end product of the proteid metabolism of the body. It has the formula $CO(NH_2)_2$. It is a crystalline solid, soluble in water, colorless, odorless, with a slightly bitter taste; it is neutral in reaction, but basic in character; dilute aqueous solutions are not decomposed by boiling, but by prolonged boiling urea is hydrolyzed to ammonia and carbon dioxide; urea forms compounds with acids and also with certain salts and oxides.

Quantitative test for urea: A comparatively easy test is that of Fowler, based upon the loss of the specific gravity of the urine after the decomposition of the urea by hypochlorite. "To apply this method the specific gravity of the urine is carefully determined, as well as that of the liquor sodæ chlorinatæ (Squibb's). One volume of the urine is then mixed with exactly seven volumes of the liquor sodæ chlorinatæ, and, after the first violence of the reaction has subsided, the mixture is shaken from time to time during an hour, when the decomposition is complete; the specific gravity of the mixture is then determined. As the reaction begins instantaneously when the urine and reagent are mixed, the specific gravity of the mixture must be calculated by adding together once the specific gravity of the urine and seven times the specific gravity of the liquor sodæ chlorinatæ, and dividing the sum by eight. From the quotient so obtained the specific gravity of the mixture after decomposition is subtracted; every degree of loss in specific gravity indicates 0.7791 gram of urea in 100 c.c. of urine. The specific gravity determinations must all be made at the same temperature; and that of the mixture only when the evolution of gas has ceased entirely." (Witthaus' *Manual of Chemistry.*)

In *nephritis,* urea is generally diminished, and also varies periodically.

A sudden diminution in quantity is a danger signal.

4. *Alcohols* are hydroxides of hydrocarbon redicles, and are capable of entering into double decomposition with acids to form esters and water. They are classified as monoatomic or monohydric, diatomic or dihydric, triatomic or trihydric, etc., according to the number of hydroxyl groups (OH) they possess.

5. Iodoform. *Formula:* CHI_3. *Preparation:* By heating alcohol, iodine, and potassium bicarbonate:
$C_2H_5OH + 2I_2 + 2KHCO_3 = 2KI + 3H_2O + 2CO_2 + 2CHI_3$.
Physiological effects: Analgesic; disinfectant (this has been denied); it may cause delirium, mania, or collapse; it weakens and accelerates the heart.

6. An *Ether is* the oxide of a hydrocarbon radical. In *simple ethers* the radicals are the same, as $(C_2H_5)_2O$, ethyl ether; in *mixed ethers* the radicals are different, as $CH_3.C_2H_5O$, methyl ethyl ether. A *compound ether* is a substance derived from an acid by replacing the hydrogen of the acid by a hydrocarbon radical, thus $C_2H_5NO_2O$, ethyl nitrate or nitric ether; compound ethers are now generally called *esters.*

Sulphuric ether is an old (and incorrect) name for ethyl ether $(C_2H_5)_2O$.

7. *Benzine* is a derivative of methane, CH_4. It is not a definite compound, and so has no formula; but it consists of hexane, heptane, octane, etc., and is used as a solvent for paints and varnishes. It is very inflammable and has a strong and characteristic odor.

8. Arsenic is an element, with symbol As, atomic weight of 75, molecular weight of 300, valence of three or five; it generally occurs in combination with sulphur; is a brittle, crystalline solid, or an amorphous powder, insoluble in water. It is poisonous. If pure it has no odor or taste. It is used in the manufacture of fly poison, rat poison, shot, pigment, and fireworks. It is prepared by heating arsenic trioxide and charcoal.

9. *Reinsch's test for arsenic is as follows:* To the suspected fluid add a little pure HCl; suspend in the fluid a small strip of bright copper foil, and boil. If a deposit forms on the copper, remove the copper, wash it with pure water, dry on filter paper, but be careful not to rub off the deposit. Coil up the copper, and put it into a clean, dry glass tube, open at both ends, and apply heat at the part where the copper is. If arsenic is present there will appear in the cold part of the tube a mirror, which will be found on microscopical examination to consist of octahedral crystals of arsenic trioxide.

OBSTETRICS.

1. See Williams' "Obstetrics" (1909), pages 35, etc.; or Hirst's "Obstetrics" (1909), pages 45, etc.

Function of ovaries: To develop ova, and an internal secretion.

Function of Fallopian Tubes: To carry ova to the uterine cavity.

Function of uterus: To receive, and lodge the fecundated ovum; to retain the fetus till it is mature, then to expel it.

Function of vagina: During coitus it receives the penis; during parturition it becomes part of the birth canal; it also serves as a channel for the escape of the menstrual and other uterine secretions.

2. *Traction on the child* may cause abrasions, contusions, laceration of skin, depression or fracture of cranial bones, laceration of blood-vessels, temporary facial paralysis from injury to facial nerve.

Traction on the placenta tends to pull the placenta flatwise (like a button in a button hole) and thus obstructs its egress, also to cause inversion of the uterus, and to tear cord or placenta and leave portion of placenta behind.

3. See Williams' "Obstetrics" (1909, pages 332 and 904; or Hirst's "Obstetrics" (1909), pages 348 and 645.

4. See Williams' "Obstetrics" (1909), pages 346 and 357; or Hirst's "Obstetrics" (1909), pages 373 and 928.

5. *Eutocia* is normal labor which terminates without artificial aid and without injury to mother or fetus.

Dystocia is labor which without artificial aid would be difficult or impossible, or dangerous to mother or fetus.

See Williams' "Obstetrics" (1909), pages 658, etc.; or Hirst's "Obstetrics" (1909), pages 439, etc.

6. See Williams' "Obstetrics" (1909), page 660; or Hirst's "Obstetrics" (1909), page 439.

	COMPLETE INGUINAL HERNIA	CONGENITAL HYDROCELE.	ACQUIRED HYDROCELE.
1. Location	Swelling continuous with inguinal region.	Same as hernia.	Swelling terminates at upper end of scrotum, can feel cord above tumor.
2. Impulse	Distinct on coughing.	No impulse.	No impulse.
3. Translucency	Not translucent, as a rule. Rarely so in children.	Translucent.	Translucent unless greatly thickened sac.
4. If reduced	Feel gurgling if contains intestine, reappears rapidly on coughing.	Reduction very slow. Reappears slowly.	Cannot be reduced.
5. Relation to testis and cord	Lies above or in front of testis and in front of cord.	Same as in hernia.	Lies in intimate relation to testis, latter felt usually below and behind tumor.
6. Palpation and percussion.	Soft, semi-elastic; dull if omentum; tympanitic if intestine.	Harder and more tense; dull on percussion.	Pear-shaped swelling; harder and tense; dull on percussion.

PRACTICE.

1. See French's "Practice of Medicine" (1910), pages 587, etc., and 603; or Osler's "Practice of Medicine"(1909), pages 796, etc., and 802.
2. See French's "Practice of Medicine" (1910), pages 151, 156, 171, and 174; or Osler's "Practice of Medicine" (1909), pages 164, 172, 188, and 189.
3. *Pulse* is the rhythmical dilatation of an artery due to the increased volume of blood thrown into the vessel by the cardiac systole.

Tachycardia is found in: Exophthalmic goiter, fevers, heart diseases.

Bradycardia, in jaundice, aortic stenosis, some brain diseases.

Intermittent pulse, in myocardial disease, dyspepsia, excessive use of alcohol or tobacco.

Irregular pulse, in mitral regurgitation.

Dicrotic pulse, in typhoid fever.

Corrigan's pulse, in aortic regurgitation.

Small pulse, in mitral stenosis, Bright's disease.

4. See French's "Practice of Medicine" (1910), pages 910 and 915; or Osler's "Practice of Medicine" (1909), pages 686 and 690.
5. *Leucocytosis* is an increase in the number of white blood cells.

Leucopenia is a reduction in the number of white blood cells.

Four diseases in which the leucocytes are increased: Leukemia, pernicious anemia, diseases of the lymphatic glands, and inflammatory conditions.

Four diseases in which the leucocytes are normal or diminished: Typhoid, malaria, influenza, and measles.

6. See French's "Practice of Medicine" (1909), pages 965, 973, 978, and 974; or Osler's "Practice of Medicine" (1909), pages 408, 419, 425, and 420.
7. *Dropsy* "is the accumulation of a watery fluid in one or more of the serous cavities, or a diffusion of such fluid through the areolar tissue of the body or its organs, or a combination of these conditions."—(Butler.) It may be found in heart disease, nephritis, cirrhosis of the liver, and aneurysm.

See French's "Practice of Medicine" (1910), page 891; or Osler's "Practice of Medicine" (1909), page 591.

8. *Some common forms of tuberculosis:* Acute miliary tuberculosis, pulmonary phthisis, fibroid phthisis, tuberculosis of serous membranes, tuberculosis of lymphatic glands, tuberculosis of genitourinary organs.

See French's "Practice of Medicine" (1910), page 397; or Osler's "Practice of Medicine" (1909), page 352.

Connecticut.—During the year 1910 there were eighty-four candidates for a certificate to practise medicine in this State. Of these sixty-one, or 72.6 per cent., were successful, and twenty-three, or 27.4 per cent., failed. This is the highest percentage of failures ever recorded in this State.

Kansas.—Of the seventeen applicants who were examined the second week in October before the Kansas State Board of Medical Registration and Examination, eight were successful. The board conducted the examination in the assembly rooms of the National Hotel in Topeka and voted to hold all future meetings at the same place. This means that no more meetings will be held in Kansas City, Kan., as has been the custom in the past. The board meets on the second Tuesday in February, June and October of each year.

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ended November 25, 1911:

	Cases	Deaths
Tuberculosis Pulmonalis	405	170
Diphtheria	260	15
Measles	154	2
Scarlet Fever	178	2
Smallpox	2	—
Varicella	217	—
Typhoid Fever	87	14
Whooping Cough	42	1
Cerebrospinal Meningitis	5	2
Malarial Fever	—	—
Totals	1350	206

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended November 24, 1911:

CHOLERA

Places	Date	Cases	Deaths
Algeria: Algiers	Sept. 1–30	1	1
Ceylon: Colombo	Oct. 1–7	1	1

THE CORRECTION OF NASAL DEFORMITIES BY MECHANICAL MEANS AND BY THE TRANSPLANTATION OF BONE.*

By WILLIAM WESLEY CARTER, A.M., M.D.,

NEW YORK,

ASSISTANT SURGEON MANHATTAN EYE, EAR, AND THROAT HOSPITAL.

"AN INCH off the end of a man's nose makes a lot of difference." This axiom embodies the mainspring of cosmetic rhinological surgery, and sounds the keynote to the situation, namely, that the appearance of the individual is to a large extent dependent upon a symmetrical nose and one bearing a correct proportion to its facial environment. Any departure from this is a blemish, but it is only when there is a pronounced deformity that the case comes under our present consideration.

It is necessary for me to review briefly some of the work that I have already published, and with which, no doubt, many are familiar, in order that I may make clear my position in regard to the correction of nasal deformities; namely, that in all cases correction should be attempted either by the readjustment of the displaced parts, or when there is a deficiency in construction material, that this should be supplied from some other part of the patient's body. This review is necessary also in order that we may make a clear differentiation between the cases adapted to each of these methods.

It is my purpose in this paper to describe these two methods of procedure, to report the clinical results obtained, and to record the conclusions I have drawn from this experience. Though it would please me greatly to review the excellent work done by those who have labored in this field of surgery, the time allotted me does not permit of this digression.

Nasal deformities from a broad surgical point of view may be divided into: (1) Those without loss of bony tissue. (2) Those in which a portion, or all of the bony framework of the nose has been destroyed either by disease or by traumatism. In the first class of cases, which are usually traumatic, we have all of the bone originally in the nose, and in addition, if the case is an old one, the callus formed about the displaced fragments. In such cases and in recent fractures of the nose I have found the bridge-splint operation most effective. For this reason, and because of an enlarged experience gained by the use of this method during the past five years, I feel that I may be pardoned for again describing an operation which, no doubt, is familiar to many.

*Read at the annual meeting of the American Academy of Ophthalmology and Oto-Laryngology, at Indianapolis, Ind., September 26, 1911.

The bridge-splint consists of a fenestrated steel bridge, the wings of which are connected by a hinge. The distance to which these wings may be separated is regulated by a thumb-screw. The second part of

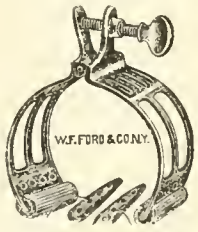

Fig. 1.—Bridge and intranasal splint for correcting depressed deformities of the nose.

the instrument consists of two hard rubber splints perforated by several small holes. The instrument depends for its efficiency upon the fact that when properly placed in position it exerts force along the lines that would tend to construct a perfectly symmetrical nose. In other words it duplicates as nearly as possible the forces employed by Nature in the development of the flattened nose of the infant into the more shapely organ of the adult. When applied in a case of depressed nasal bridge, its influence directly opposes the forces that produced this deformity.

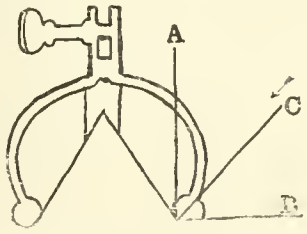

Fig. 2.—Illustrating the mechanics of the intranasal splint and bridge.

Application of the Instrument.—Let us assume that we have a recent fracture, or, in the case of an old deformity, that the bony structure of the nose has been thoroughly mobilized by means of the author's special chisel and chisel-forceps in the manner described in my previous presentation of this subject.* A piece of No. 14 silk is passed through one of the holes in the hard rubber splint and knotted, or preferably a splint molded from gutta-percha to suit the case is used. The other end of the suture is threaded into a medium-size curved needle; this is passed from within the nose through the cartilaginous dorsum just below its attachment to the nasal bones. This operation is repeated on the opposite side and the splints are adjusted to the roof of the nose. The bridge is then applied and the wings, the edges of which have been previously padded with gauze, are adjusted by means of the thumb-screw so as to give the proper support to the

**Journal of the American Medical Association*, December 4, 1909.

base of the nasal triangle. The dorsum of the nose is then pulled up into its proper position by means of the sutures and the latter are tied together over the hinge of the bridge. The instrument is left in position for about two weeks. If the bridge is anchored to the forehead by means of adhesive straps the patient need not be confined to bed after the second day.

I have operated upon about fifty patients by this method. This series includes recent fractures, old depressed, irregular, and lateral deformities. There were only two failures, and these occurred early in my experience before I fully realized the limitations of the operation, namely, that it is not applicable when there is insufficient bony framework to support the nose after the removal of the bridge. In several instances it was necessary to do the submucous operation before correcting the external deformity; but in the majority of the cases the intranasal deformity was corrected by the bridge-splint operation. This is one of the strongest arguments in favor of the latter procedure. In many cases I found that the septum was so short that it did not permit of the bridge being raised. In these instances, in order to lengthen it, I incised the septum from the floor of one nostril diagonally through to the roof of the other. This allowed the upper segment to slide by the lower when the bridge was raised without leaving a perforation. My experience during the past five years and the present condition of the patients operated upon enable me to give this method of treating nasal deformities my hearty endorsement.

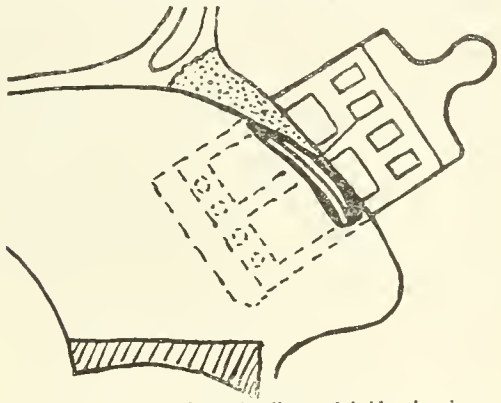

Fig. 3.—Sectional view of splint and bridge in place.

The following observations, drawn from this experience, may be worthy of record: (1) Great care should be exercised in the selection of cases. No case should be attempted by this method alone, where there is not a sufficient amount of bony framework to support the nose after the removal of the bridge. In certain cases, however, where it is necessary to transplant bone, the bridge-splint is a valuable adjunct. In these cases it does not seem to complicate the operation. (2) The bony framework must be thoroughly mobilized, and when the septum is too short it must be lengthened by the incision previously described. (3) The wings of the bridge must be well padded with gauze and the skin upon which these rest must be frequently inspected and bathed with alcohol, lest pressure necrosis occur at these points. (4) The intranasal splints must be made to conform to the roof of the nose. It is best to mold these out of guttapercha to suit each case. (Personally I never use the splints that come with the instrument.) (5) The liberal use of vaseline in the nose following the operation greatly relieves the tumefaction of the tissues and lessens the liability to infection. (6) Casts both before and after the operation should be made.

Nasal Deformities Attended by Loss of Bone.—The treatment of nasal deformities where there has been a loss of bony framework is an entirely different problem; the use of the bridge-splint being inadequate, because there is nothing to retain the shape of the nose after the removal of the bridge. For these cases little has hitherto been done, and no satisfactory expedient for their relief has been adopted. They are unsuitable for paraffin on account of the large amount of fibrous tissue which is always present, and then too there is no solid foundation upon which the latter can rest. Paraffin, even though it be skillfully injected, may spread into undesirable locations; or if properly placed it may later shift its position. At best it is a foreign body, and as such is subject to the uncertainties that surround such substances when held in the living tissues. The essential element lacking in the cases is bone, and this must be supplied.

The efforts of those who have experimented in this field of surgery have been confined chiefly to supplying defects in the long bones and those of the skull. It has been demonstrated by these men (1) that the autoplastic operation, *i.e.* the transference of bone from one part of the body to another, gives the quickest and best results; (2) that homoplastic transplantation, *i.e.* from one animal to another of the same species, is frequently successful; (3) that heteroplastic transplantation, *i.e.* from one animal to another of a different species, is unsuccessful. Most of these observers believe that it is necessary to include the periosteum with the bone graft. With this view I do not concur for the following reasons: (1) Soft tissues (which would include the periosteum) are successfully transplanted with much more difficulty than bone. (2) When the bone is introduced into the nose we desire only that it shall be nourished, and that it shall remain *in situ*. We do not desire to grow bone, hence we can dispense with the osteogenetic layer of the periosteum. (3) The bone when deprived of its periosteum comes in more intimate contact with the soft tissues which surround it in its new location and from which is quickly formed an envelope of connective tissue which nourishes it.

In my work in this field I have confined myself to the autoplastic operation, the rib having been selected for transplantation for the following reasons: The ninth rib, at about its middle, is thinly covered by muscle; a segment at this point can be easily shelled out of its periosteum. The operation causes the patient little discomfort and the rib is promptly regenerated from the periosteum. (2) The rib is especially adapted for transplantation into the nose because of its shape and structure; the slight curve being an advantage. The fact that the rib is richly supplied with minute nutrient foramina favors its nutrition when introduced into the tissues of the nose. For these reasons also it is a bone which may be used to advantage in general surgery when it is necessary to transplant bone to supply defects in the long bones, bones of the skull, &c.

Description of Bone-Transplantation.—The following is a general description of the operation, which I have performed nine times. It has been modified in some instances to meet special requirements, but these modifications will be referred to later in the specific report of these cases. The skin over the nose and over the right side of the chest corresponding to the ninth rib is prepared for an

aseptic operation. A curvilinear incision (convexity downward) about ¾ of an inch long is made down to the bone over the nasofrontal process. Through this incision the skin and subcutaneous tissues over the dorsum and sides of the nose are elevated with a long, thin, two-edged knife, curved

Fig. 4.—General view of the bridge after its application to the nose.

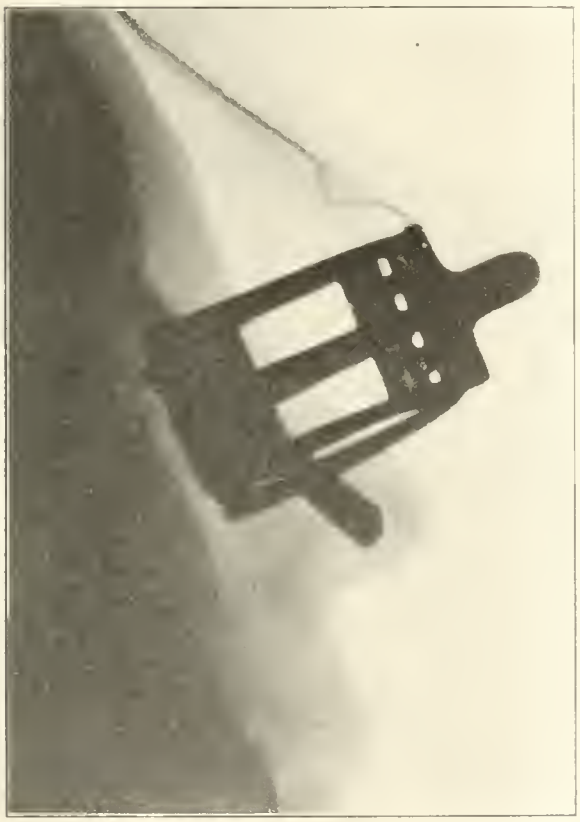

Fig. 5.—X-Ray plate showing bridge-splint and intranasal splints.

on the flat. Above this incision the periosteum over the nasofrontal process is elevated for about a quarter of an inch. This wound is then covered with sterile gauze. The ninth rib, at about its middle, is then exposed, and a portion two inches long is shelled out of its periosteum and removed. I then split this section of rib in its transverse diameter. All of the medullary tissue is then carefully scraped from the outer half and the thin strip of compact bone is shaped to suit the deformity. If the medullary tissue is not removed from the transplanted bone, it has been found that it causes irritation and an aseptic fever, the graft being more apt to slough out. It is desirable to transfer the bone to the nose as quickly as possible and that too without placing it in any solution. The strip of bone is inserted into the wound in the nose previously made for its reception, the lower end reaching nearly to the tip of the nose, and the upper being carefully anchored under the periosteum over the nasofrontal process. This latter procedure is greatly facilitated by turning up the curved flap made at the time of the original incision. The wound is closed with horse-hair sutures and dressed with sterile gauze. If the case is progressing satisfactorily the dressing is not disturbed for a week.

Several of the following cases are from Dr. Harmon Smith's clinic at the Manhattan Eye, Ear, and Throat Hospital; the first three of these, having been previously reported, are mentioned again for the purpose of showing their present condition.

Case I.—This patient was a little girl, aged 6, who, when two years old, fell on her nose, fracturing it. The nose retained its infantile type, developing broad and flat and scarcely protruding beyond the level of the face. No nasal bones could be demonstrated. After the operation, which was performed on June 21, 1910, the profile was almost perfect and has remained so up to the present time.

Case II.—A woman, aged 25, who fell on her nose when she was 7 years old, the injury being followed by a septal abscess. In this case there was no history of syphilis, and the woman says that she always enjoyed the best of health. The deformity was marked, and was of the flattened, concave variety. Operation was performed on June 25, 1910. In this instance the concavity was so great that two

Fig. 6.—Bone-transplantation for nasal deformity. The central figure shows the method of raising the skin and subcutaneous tissue; the insert figure shows the bone in place.

layers of bone grafts had to be superimposed. The bridge is completely reconstructed, and has remained so. The bone is firmly imbedded, and the x-ray plate seems to show that bony union has occurred between the two implanted fragments.

Case III.—A railroad man, aged 47. This pa-

tient claimed to have been perfectly healthy previous to a railroad accident in which his nose was injured, the injury being followed by erysipelas, when much bony tissue sloughed out. Since my first report of this case I have been informed by the physician who attended him at the time that the injury to his nose was trivial, and that his deformity

Fig. 7.—Nasal deformity attended by loss of bone. Case III. H. C. W., before bone-transplantation operation.

was due to syphilis for which he received treatment. The bridge was badly depressed and flattened, and a large scar bound the skin to the subjacent tissue. The septum was almost completely destroyed. The case presented a very unfavorable outlook for correction by any method of treatment. The operation was done October 20, 1910. The normal contour of the nose was immediately restored. The grafted bone acted as a rafter, and, being firmly supported by the nasofrontal process, which served as a fulcrum, it continued to exert a gradual traction on the soft tissues of the nose, which, having been unsupported, had subsided into folds on either side of the nose. These folds constitute one of the most

Fig. 9.—X-Ray plate showing transplanted bone in position.

disagreeable features of depressed nasal deformities. In this case, within two weeks, the folds had completely disappeared, the tissue having been drawn up into it proper place in the nose. The result in this case was practically perfect. I have recently heard from this patient, and he assures me that the good results have been maintained.

Fig. 8.—Case III. H. C. W., after bone-transplantation operation

Case IV.—A woman, 38 years of age, fell from her cradle when she was three years old, striking on her nose; the injury was followed by a septal abscess. There is no history of syphilis. The nose retained its infantile type, being broad and flat. The deformity became much more marked at about the age of 18. When she was 21 years old she consulted Dr. William T. Bull, who put a silver bridge into her nose: this sloughed out in a short time. She then came under the observation of Dr. Robert F. Weir, who introduced a celluloid bridge; this also promptly sloughed out. Owing to the extensive sloughing that had occurred, the nasal bones and the septum had been completely destroyed, and the nose was a mass of scar tissue. The nasal deformity was much more pronounced, and in addition both nostrils were completely closed by cicatricial tissue. Four years ago she came to Dr. Harmon Smith, who restored the integrity of the nasal passages and injected paraffin into the bridge, partially building it up. The improvement was great, but there still remained some depression and the cheek folds were very pronounced. About a year ago she noticed a deep furrow developing across the nasal bridge. In March, 1911, she returned to Dr. Smith, who noticed that there had been some shifting upward of the paraffin. On account of the large amount of scar tissue present he did not regard it as a case for further prosthesis and referred it to me for bone-transplantation. The operation was done March 10, 1911. After removing the paraffin, which came out *en masse* from its capsule of connective tissue, I found that there was absolutely no support for the bone-graft. In order to support the dorsal piece, reaching from the nasofrontal process to the tip of the nose, I made an inverted V-shaped pier out of two additional pieces of bone; these were introduced through the same wound. The apex of the pier rested under the dorsal strip of bone and the other ends on the superior maxilla on either side of the nasal notch. This framework supported the nose in its correct position, so that the wound was closed in the usual manner. Healing occurred promptly, and but for a slight infection which became apparent on the tenth day, and which re-

sponded to treatment, recovery was uneventful, the patient being discharged from the hospital on March 30, twenty days after the operation. The result, though satisfactory to the patient, could, I believe, be improved by grafting in another piece of bone, as we now have a firm foundation upon which to work.

Fig. 10.—Case IX, specific deformity, before bone-transplantation operation.

Case V.—A young man, aged 21, no specific history. This patient's nose was fractured several years ago by a blow from a baseball bat. The nasal bridge was broad, flat, and depressed. There was considerable nasal obstruction, due to a thick, irregular septum. The operation was done May 10, 1911. In addition to bone-transplantation, I did also the bridge-splint operation; the latter procedure being necessary in order to relieve the nasal obstruction and make the nose narrower by bringing the nasal processes of the superior maxillæ nearer together. Both operations were done at the same time, and neither proved to be a menace to the other. Recovery was uneventful and the result was entirely satisfactory, and has remained so.

Case VI.—A married man, aged 31 years, the father of two healthy children. This patient had syphilis eight years ago, was treated for eight months. There being no signs of the disease, he discontinued the treatment. Five years ago there began a profuse fetid discharge from the nose, and several pieces of bone came away. He immediately began treatment and has kept it up more or less continuously ever since, under the guidance of his physician. Three years ago the bridge of his nose began to fall in. Examination showed the nasal bridge to be considerably depressed and flattened. The nasal bones were slightly separated, and running down the center of the nose was a deep furrow, giving one the impression that the upper edge of the septum had dropped from its position between the lateral cartilages; and this no doubt had occurred. The septum was completely destroyed, and there was a large hole in the hard palate, which he covered with an obturator when speaking. The nose and throat were filled with cicatricial tissue, and he was suffering from a very foul rhinopharyngitis atrophica. The Wassermann test was negative. Bone transplantation was done June 14, 1911. Recovery was uneventful and the excellent result obtained in this case has remained up to the present time.

Case VII.—A young man, aged 31 years, having a congenital depressed deformity and pug-nose. No specific history. Bone transplantation July 6, 1911. Recovery uneventful. Deformity completely corrected and has remained so.

Case VIII.—A young man 21 years of age, practically blind from choroiditis. No specific history. Patient ran into a post three months ago and fractured his nose. On examination the nasal bones were found intact and in correct position, but the entire cartilaginous dorsum had caved in, producing a hooked deformity. Bone transplantation was done July 18, 1911. The deformity was completely corrected. Seven days after the operation there was some inflammation at the site of the incision; the wound was opened and irrigated. After this healing took place promptly and the patient was discharged from the hospital on August 3, sixteen days after the operation. The result in this case was entirely satisfactory and has remained so.

Fig. 11.—Case IX, after bone-transplantation operation.

Case IX.—This was by far the most difficult case that I have attempted. This patient, a young man 28 years of age, had been healthy up to eight years ago, when he contracted syphilis. The secondary symptoms were most severe, and he was confined to his bed for some time. He has been under treatment at Hot Springs almost continuously during the past three years, and at times has taken as high as 320 grs., of potassium iodide per day. Six years ago the nose became involved and large pieces of bone sloughed out, later a very pronounced deformity developed. Examination showed a very bad depressed nasal deformity. The tip of the nose was elevated and the nasal bridge was folded back upon itself at such an acute angle that free nasal respiration was rendered impossible. The nostrils pointed directly forward. The septum, hard and soft palate were almost completely destroyed. Cicatricial tissue was present in abundance and there was present a foul and very active purulent rhinopharyngitis. The patient's general physical condition was poor. The Wassermann test was negative at the time of the operation, which was performed July 31, 1911. Owing to the acute angular depression of the bridge, the tissues were elevated only with great difficulty. It was found necessary, on account of the large amount of dense cicatricial tissue, to elevate over the entire nose and far out under either cheek. When the bone graft was inserted, the tension on the skin was so great that it became blanched. This tension was relieved by the bridge-splint operation, which was rendered necessary in order to restore the integrity of the nasal chambers. The bridge-

splint was removed at the end of a week. The result was very satisfactory, both from a cosmetic and functional point of view. Sixteen days after the operation there was a slight bulging on the right side of the nose. An incision was made and a small amount of pus evacuated. The wound was irrigated for a few days, and the discharge having almost ceased the patient, on account of urgent business, was allowed to return to his home in the West. I have recently seen this patient; the discharge has ceased completely and the deformity remains corrected. I believe that the primary good result will be maintained, for the firm implantation of the bone seems not to have been affected by the infection, which I feel confident came from the nasal cavity. The rib in this case presented a very interesting condition; the compact bone was very thin, and extremely brittle, so much so that I found it difficult to shape a piece to suit the deformity. I attributed this to the virulence of the disease and the large amount of potassium iodide that the patient had been taking for a long time.

It is interesting to note that in none of these cases did the introduction of bone into the tissues seem to cause the slightest irritation. This I believe is due to the fact that the transplated bone is of the same chemical constitution as the surrounding tissue; there is, therefore, no antagonism between the two. None of my patients had any fever, and all were discharged from the hospital within ten days, with the exception of Case VIII, which was in the hospital two weeks.

The mechanics of the operation involve the principle of the lever; the short arm is fixed beneath the periosteum; the nasal process of the frontal or the nasal bones as the case may be act as the fulcrum, and the long arm of the lever does the work of lifting up the depressed bridge. The long continued lifting power of this lever elevates the objectionable cheek folds into their proper position in the sides of the nose, and this is one of the most desirable effects produced by the operation. There is left beneath the transplanted bone a pyramidal space which immediately becomes filled with a blood-clot, and which in the ideal operation becomes organized. The conditions here are extremely favorable for the introduction of infection; and this I believe will occasionally occur in spite of every precautionary measure. It is interesting, however, to note that infection does not necessarily mean a failure of the operation.

It would seem that syphilitic deformities are amenable to this method of treatment, provided that the disease has been cured, or at least mitigated, as shown by a negative Wassermann reaction. These cases, however, are more difficult on account of the large amount of cicatricial tissue, the atrophic rhinitis, and the general condition of the patient. It is my belief that the transplanted bone continues to live in its new position, and that it receives its nourishment from the surrounding tissues through the medium of an envelope of connective tissue which quickly forms about it.

In this work I have not hesitated to attempt the most difficult cases, and in some instances those which were seemingly hopeless. I feel, therefore, that the efficiency of this method of treating a class of cases for which hitherto so little has been done has been subjected to a fair test, and that the results obtained should commend it to your serious consideration.

PEDIATRIC MEMORANDA.*

MEGACOLON CONGENITUM. ATRESIA ANI ET INTESTINI RECTI.

By HERMAN B. SHEFFIELD, M.D.,
NEW YORK.

1. *Megacolon Congenitum.*—The classical form of congenital megacolon is the one which is manifested immediately after birth by obstinate constipation, intense meteorism, and retention in the colon of comparatively large quantities of fluids injected for the purpose of emptying the lower bowels. Since the first description of the disease by Dr. Hirschsprung in 1880, however, there has been a growing tendency to include under this heading also the cases developing several weeks or months after birth, as long as they are traceable to some congenital intestinal anomaly, such as constriction,

Fig. 1.—Megacolon Congenitum.

kinking, or displacement of the lower portion of the colon or rectum. The case I am about to describe belongs to the latter category. The child was apparently robust at birth; passed meconium the same day, and continued to have several thin movements daily for several weeks thereafter. Her stools were often green and mixed with mucus, especially after passing through a severe attack of colic, but as she was breast fed, no particular attention was paid to the intestinal disturbance. When six months old, or thereabouts, the baby's dietary was enlarged by the addition of zwieback, thin gruel with milk and baked potato with butter, and it was about this time that obstinate constipation and pronounced meteorism made their appearance. At first the constipation was relieved by laxatives, and later these and enemas had to be resorted to. If left constipated, the child would greatly suffer from colic, occasional vomiting, and

*See pages 913 and 1062.

after administering an active cathartic, the stools would be found mixed with large quantities of mucus in the form of irregular pieces of membrane and, now and then, also with blood. The child was treated in several clinics and by private physicians, but notwithstanding faithful compliance with the prescribed dietaries and the application of different therapeutic measures, her condition grew perceptibly worse. The little patient came under my observation at about three years of age. As can readily be seen from the accompanying illustration (See Fig. 1) the abdomen was immense in size. It was as tense as a kettle drum, glossy and bluish in color, and traversed by numerous tortuous veins. She was greatly emaciated, and showed marked symptoms of rachitis, hence on the first examination it appeared to me that I was dealing either with a pronounced case of rickets or tuberculous peritonitis, more probably the latter, since her temperature at the time was 1½° F. above normal. As the mother was reluctant to leave the child in the hospital, I prescribed an antirachitic diet, and the syrup iodid of iron in

Fig. 2.—Atresia Ani et Recti.

an emulsion of cod liver oil, and directed her to report to me twice a week at the outdoor department. The child's condition grew worse from week to week, and, finally, after six weeks' futile therapeutic efforts, she was admitted to the hospital. By this time I was fully convinced that the lesion was somewhere in the colon, consisting of an obstruction probably of tuberculous nature: she vomited repeatedly, lost greatly in weight (weighed only 18 lbs.), ran an irregular temperature of from one to two degrees F. above normal, and was invariably constipated, unless given an active cathartic, which with intense pain produced a watery movement containing mucus and traces of blood. Digital examination of the rectum proved negative. I referred the patient to the late Dr. Th. H. Manley for operation. On opening the abdomen we found the descending colon widely dilated, cornet shaped, its widest extremity (measuring about 6½ inches in circumference) terminating at the sigmoid flexure. At this point the intestine was abruptly contracted, scarcely measuring 1 inch in circumference, and continued at the same width down to the rectum.

The surgeon wisely decided to leave the patient alone, for she was barely alive when removed from the operating room. She died the following day. Judging by the findings at the operation we gained the impression that her life would probably have been saved had an operation been undertaken a year or so earlier.

2. *Atresia ani et recti.*—This case is of interest principally from a teratological point of view. The family history presented nothing extraordinary. It was the first child and born at full term. The mother suffered greatly during the entire pregnancy and claimed not to have felt life until about the middle of the sixth month. The child was delivered instrumentally, after Dührssen incisions, by Dr. A. Sturmdorf (who kindly referred the case to me). It was a monstrosity from head to foot. (See Fig. 2.) The head was soft and deformed, the ears were turned inward and hung loosely like those of a dachshund, the forearms were contracted, the legs were short and sharply curved inward, and the feet in *talipes varus* position. Scrotum and its contents were absent, and a thick, flat imperforate piece of skin represented the penis. There was no anus nor even an indication of one. On opening the abdomen we found that the intestines terminated at the left iliac fossa in a large blind pouch filled with meconium. The kidneys and bladder were rudimentary. The thoracic organs were apparently normal in development. The mother has since been more fortunate with the second child, though this one also shows slight deformities of the ears and fingers.

THE ODYSSEY OF A DIAGNOSIS.

By CECIL KENT AUSTIN, M.D.,

PARIS, FRANCE.

The many methods of physical exploration of the body that have been introduced into medical practice during the last generation, and in particular the *x*-ray, have of course very materially improved our chances of attaining accuracy of diagnosis; in correlation with this progress, however, must be admitted the counterpart, that they have undoubtedly widened, to a considerable extent, our liability to error—to give only one instance, through faulty interpretation of images. The humiliating history of the following case is so much to the point, in this connection, that it has seemed worth bringing to the notice of the medical public.

There is in medicine an old and unfortunately very true saying, that it is through our mistakes that we advance in knowledge; just at present certainly no one is more fully convinced of the truth of this axiom than the five medical men who were called on to examine this patient. By a fortunate occurrence the notes on the case were committed to paper at each of its successive phases; they give, therefore, a very exact picture of the widely differing views held at its various stages. Brief consideration, then, of the startling vicissitudes through which this diagnosis passed will enable the reader to form an idea of the chastened frame of mind in which the above-mentioned physicians found themselves when the facts of the situation were finally revealed.

The patient, a married woman of fifty, had had

two children; one is now a grown man, the other died of some indefinite disorder at eight months of age in charge of relatives in the country. There had been no miscarriages. Twenty-six years ago she had a severe attack of left pleurisy with effusion, which resorbed spontaneously. I had known and visited this patient for over ten years, during which she had on the whole appeared well and cheerful. The relatives about her, however, said that for some time past she had been complaining a good deal, and in particular, during the last five years, of neuralgic pains in the lower left anterior portion of the thorax, apparently more noticeable before her periods. This symptom had, however, not seemed very important, and was laid to intercostal neuralgia or rheumatism.

About two and a half years ago she began to manifest what appeared to be an idiosyncrasy for tobacco; the odor of this smoke became sufficient at any time to induce retching, during which she would bring up a mucous secretion, or, if soon after a meal, the food she had eaten. These efforts would continue until nothing remained to come up, and so sensitive did she become to tobacco that it was not even necessary for anyone to actually smoke in her presence, the mere fact that a person smelled of smoke was enough to bring on the nausea. In the matter vomited the patient never noticed any remnants of food of former meals; nor had she in previous years ever manifested any special sensitiveness to tobacco. In the early part of April, 1911, she began to complain, quite suddenly, of severe pain in the left side of the epigastrium, pain deep-seated, fore and aft, possibly more pronounced in the lower part of the back than in front, where it appeared to extend downward and outward toward the hollow of the flank. There was marked sensitiveness to pressure just below the left thoracic edge at the epigastrium, but that was all, neither swelling nor induration could be detected. She never vomited except when upset by tobacco; there was constipation and apprehension against taking food, and her temperature and pulse were normal.

I knew that this woman led a life at high pressure, under severe and unquestionable nervous strain; so my first diagnosis was acid dyspepsia, and I prescribed the diet and alkaline treatment that usually relieve such cases very promptly. My surprise was therefore considerable when after a few days I found the situation practically unchanged; and it became greater still when in one of the patient's attacks of tobacco-nausea she experienced a severe tearing sensation in the left side of the epigastrium, and the pain became intense, necessitating the use of opium. The idea of perforated ulcer was naturally the first to occur to the mind; but after watching her closely and finding no signs of acute general reaction of the peritoneum I asked a surgeon to take a look at her with me to see whether she might not be developing a subphrenic abscess. He, however, could detect nothing surgical, and I continued to follow the case with attention. A milk of bismuth treatment was next tried, but it likewise gave no appreciable result.

The situation so far had, consequently, summed itself up entirely in the symptom *pain*; and pain *in the abdomen*, not at all in the thorax. Although the patient complained that the taking of food caused her much suffering, that was manifestly not the real cause of the pain; besides, her nights as a general thing were worse than her days. Furthermore, she was by this time eating so little that that alone could not possibly account for her distress. She next spoke to us of a very curious sensation, and this feature opened the second, or *obstruction* phase of the case. She said that not only was the swallowing of food painful, but that she had a feeling as though what she ate went down *in successive stages,* like a child descending a series of steps, one at a time; nor could she any longer take very much at one meal, as it did not seem to pass. The symptoms had, however, so far been so exclusively abdominal that the idea of any esophageal disorder never entered our heads, and we laid this fresh development either to the patient's imagination, or possibly to a spastic condition of the esophagus due to her suffering and nervous irritability.

The patient's pain, however, continuing, and the amount of food consumed being altogether insufficient, it became necessary to make further efforts to arrive at some precise diagnosis. There was neither vomiting after food, nor blood in the stools, and the pain did not in any way resemble that of ulcus rotundum or neoplasm; furthermore, the condition present had had an *acute* beginning. We were therefore evidently dealing with one of the more unusual painful disorders of the epigastric region. There were no signs of tabes, so a gastric crisis was ruled out; I thought of the pancreatic diseases, and of the uncommon forms of hernia, diaphragmatic, etc.; of abdominal angina pectoris, or arteriosclerosis of the celiac trunk; and of aneurysm of the abdominal portion of the aorta. Finally on April 19 I sent her to a medical friend with the request to examine her before the fluorescent screen, which he did in conjunction with the *x*-ray expert of his hospital.

The notes written at this moment read as follows: "This gave us at last the solution of the enigma. On the patient's swallowing a glass of bismuth emulsion, a mixture of bismuth carbonate in a solution of gum arabic, it is seen to pass down the esophagus, not into the stomach, but first into a long, stocking-shaped diverticulum, undoubtedly congenital, that opens into the esophagus at about the level of the third dorsal vertebra, and that has a pointed lower extremity advancing in the direction of the anterior mediastinum and to the *left*. This diverticulum is animated with movements communicated to it by the cardiac pulsations. It appears to have a well-developed muscular coat; when it is full a little bismuth can be made out overflowing and passing down the esophagus; a second examination, made three hours later, showed that the diverticulum had entirely emptied itself of its bismuth contents. The screen examination of the stomach is absolutely normal. In the lungs there are calcified tuberculous lymphnodes about both hili, and the apices are not transparent. To say that the result of this examination was a surprise would be to depict the situation in sober terms; a congenital diverticulum of the esophagus is not a condition that the practitioner meets with very frequently; and a diverticulum opening high up, but with an almost exclusively abdominal symptomatology, must be rarer still. Besides, how is this complete silence up to the age of fifty, followed by this sudden and extremely painful condition, to be explained? What can have been the origin of that sudden tearing sensation that the patient experienced; and what is the meaning of the present constant severe pain, mostly in the lower left side

of the back? Also, how can the patient's actual mode of alimentation be interpreted? For she now tells us that so soon as six tablespoonfuls of food are exceeded the remainder is regurgitated, spontaneously, without effort, whereas a month ago she could eat and drink like anyone else.

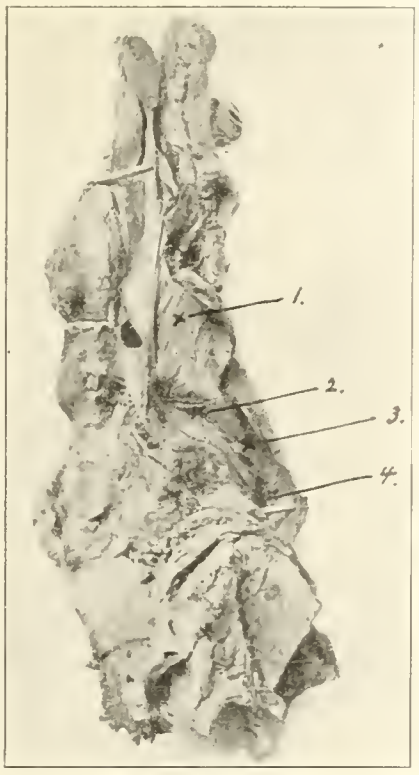

FIG. 1.—1, the dilated esophagus above the obstacle (corresponding to the vertical part of the shadow on the radiogram). 2, the deflected part of the esophagus ending in an apparent point (the horizontal part of the shadow on the radiogram). 3, point where the wall between esophagus and aneurysm was transparent (perforation made during examination of the specimen). 4, portion of esophagus below the stricture, forming a species of pocket above the diaphragm.

"The interpretation of the situation seems to be the following. Before the present condition came on this diverticulum existed in a latent state, with a non-patent, or at any rate, very small orifice, the food passing over it and on directly into the stomach. But a short time ago, and particularly at the moment of the tearing sensation, this orifice was forced open by some cause at present unknown, foreign body, or possibly owing to malignant degeneration of the edge of the orifice, and now all food swallowed passes first into the pocket, whence it is transmitted little by little to the stomach. When the pouch is full it probably presses on and flattens the esophagus, thus preventing the taking of more than a certain amount of food at one time, the index of the pouch's capacity being apparently six tablespoonfuls."

Such, then, was our opinion at this stage of the case. The next question was, naturally, what was there to be done, the patient's condition having become really serious through suffering, bad nights, and altogether insufficient alimentation. If the supposition of a sudden and forcible irruption into a hitherto virtual cavity were correct, there seemed a possibility that by putting the region at rest the orifice might be got to close again, or at least become too small to admit of the ready passage of food, although the chances of this were small, as upwards of three weeks had elapsed between the time of the supposed accident and the detection of the diverticulum. How then could the region be best put at rest? A simple means at once suggested itself, that of trying to find a position for the patient in which, while taking food, its tendency to pass into the pocket would be counteracted. The right decubitus posture seemed to succeed for a while, but we soon perceived that this plan was a delusion. We next thought of feeding with the gastric sound, or, possibly, of gastrostomy. But before proceeding any further we decided to make an esophagoscopic examination under cocaine, to verify the situation and size of the orifice, the condition of the mucous membrane about it, and, in general, to satisfy ourselves as to the safety of passing sounds down such an esophagus. Incidentally arose the question of the possibility of a radical removal of the diverticulum by means of a surgical intervention, as the outlook for the patient did not seem particularly brilliant unless some pretty active measures of relief were devised before the lapse of much more time.

On April 18 the patient had a sudden, violent and unexplained attack of tachycardia, which lasted a couple of hours, the pulse being at 180 and perfectly regular. She was at this period suffering so severely that she could hardly be persuaded to touch even liquid food, and was losing flesh rapidly. On the 19th, 20th and 22nd she had to have an injection of a quater of a grain of morphine, and on the 22nd her temperature was 98.4° and her pulse 78.

At that moment, then, we four physicians were quite convinced that our patient's condition was due to a congenital diverticulum of the esophagus, with an orifice situated high up, near the third dorsal

FIG. 2.—The aneurysmal pouch emptied of its clots. The aorta above and below the aneurysm is covered with patches of atheroma.

vertebra. We thereupon took unto ourselves a fifth excellent confrère, very skilled in the use of the esophagoscope. He, however, asked to be first allowed to examine the patient again before the screen with the bismuth test; this was done on the 23rd, with results very similar to those of the

previous examinations. A mercury-loaded catheter was also used at this séance, but it was seen to pass directly into the diverticulum and to stop at its extremity. The examination by esophagoscopy was carried out under cocaine that same evening, carefully and at leisure, and revealed further surprises. No high-situated opening into a diverticulum could be detected. The tube passed smoothly along a normal esophagus until at about 30 cm. from the upper incisors, at which point it was stopped, a crescent shaped fissure being visible just beyond, in front and to the right, with its concavity pointing back and to the left. No other opening could be found, nor was there any degeneration of the mucosa to be seen. The instrument was then removed and the patient permitted to rest, and in the meantime a small esophageal catheter was pro-

Fig. 3.—X-Ray picture showing the apparent diverticulum.

cured; the tube was then inserted a second time and the catheter passed down it, through the crescent, and into the stomach. It was then fastened to a tooth, in a breach where several were lacking, and a large feed of milk was administered by its agency. There was no doubt about the catheter being really in the stomach, as the quantity of food given, two or three tumblers at the least, was enormously in excess of anything she had been able to take for some time previously. The patient was then sent back to bed.

The next day, April 24, she was again examined before the screen, as she had vomited her milk of the previous evening, and could since then no longer be fed by the tube. A wire inserted into the catheter was stopped at the 30 cm. limit, and some bismuth, swallowed down along the side of the tube, collected in the diverticulum as before. It was evident that the catheter, which was a silk and gum one, had kinked, possibly under the strain of the vomiting the evening before. So it was withdrawn. At this séance, the patient standing in an almost transverse position, a small and indistinct portion of the shadow of an apparently round body of about the size of a mandarine orange was seen slightly overlapping the image of the point of the heart; this disc section extended a little to the left but principally downward below the outline of the heart apex, seemed less distinct than the latter, and did not pulsate. This was the first time that this detail was detected.

After these last examinations we were of the opinion that the orifice of the diverticulum must be low down in the esophagus; that the latter was considerably dilated above it, and that the pouch, when filled, pressed on and obstructed the esophagus. This is altogether exceptional in the matter of diverticula, most of which originate high up, so much so that forty or fifty of them have been removed by operation. The most probable explanation of the case, then, seemed to be that it was not a congenital pouch, but an acquired traction diverticulum, due to adhesions subsequent to the patient's pleurisy of twenty-six years ago. Our esophagoscopic friend, however, was not at all satisfied with the results of his prolonged and careful examinations; in fact, he said very plainly that the whole situation seemed to him most obscure.

Something, however, had to be done to prevent the patient's succumbing to actual inanition, and gastrostomy was performed on the following day under chloroform; the operation was very short, a Ricard apparatus was used, and the quantity of anesthetic administered was small. By one of those strange fatalities the patient's urine, which had been saved prior to operation for analysis, was heedlessly thrown away by a servant at the last moment, so that the usual tests could not be made. On the 26th all was well, and 1 liter of urine, normal in appearance, had been passed; but during the afternoon of the 27th the patient developed signs of acute postoperative dilatation of the stomach, with vomiting of blackish fluid. This was relieved at 4 P. M. by abundant flushing through the gastrostomy tube. The urine at that moment was scanty, dark, and with a thick deposit; but no special attention was paid to this, as the patient's symptoms seemed sufficient to explain the condition. When seen at 9 P. M. the vomiting had not recurred, she appeared perfectly well, and soon afterward settled down quietly to sleep. On the morning of the 28th she had passed a good night, but she was very somnolent and could not be got to answer questions properly; both thumbs were contracted tightly into the palms of her hands, and her head moved from side to side; there was also slight conjunctival subicterus. There had been 500 c.c. of urine during the 24 hours, which gave a dense precipitate with nitric acid, though the Esbach test showed next morning only 1 gram per liter. Casts were not looked for. On the day previous there had been neither headache, puffiness of the eyelids, nor sight trouble. She then became rapidly comatose. At 2 P. M.: "No urine since A. M.; sphincters normal; T. 37°; pulse 90, regular and good; R. normal, 18. Continues to turn her head from side to side on the pillow." At 9 P. M.: "Much worse; pulse 150; constant, quiet convulsions, one every minute or so." These increased in severity during the night. Toward morning, April 29, she urinated involuntarily in bed. Death occurred at 7 A.M., three days and a half after the operation, in this

uremic condition, the entire illness having lasted just four weeks.

Post-mortem, performed twenty-six hours after death, showed that we had been entirely at sea all through the case. The disorder that had given rise to the symptoms that had baffled us was in reality a small, sacciform aneurysm of the thoracic aorta situated immediately above the diaphragm; this tumor had first deflected the esophagus from its course, and then obstructed it by flattening and kinking. What we had taken for a diverticulum was the deviated and dilated esophagus running forward and to the right (*not* to the left, as one of the *x*-ray operators had asserted so positively), and finishing in an *apparent* point where it was flattened. The faint round shadow seen back of the heart apex at the last screen examination, on the 24th, which at the time was thought to be due possibly to some accumulation of bismuth, was evidently the image of this aneurysm.

All the apex of the left lung was adherent; on the right side there were slight adhesions at the apex and total symphysis of the base. On the inner portion of the right apex there was an extensive zone of scar tissue. Curiously enough, in view of the diagnosis of traction diverticulum that had been made, there was a limited area of adhesion in the left pleura corresponding to the aneurysmal tumor. The kidneys were large, the left one more so than the right, and there was intense congestion about the base of the pyramids. More careful dissection, some time later, after the specimen had hardened in a solution of formalin, gave further interesting details. Above the tumor the esophagus was uniformly distended for some distance (Fig. 1); its lower portion was thrown forward and to the right by the tumor, but then made a short and sharp turn backward and to the left, immediately above the diaphragm, forming a sort of blind pocket. The entire inside of the aorta was covered with large patches of atheroma, both above and below the pouch, and the main celiac vessel was also diseased.

The aneurysm, the size of a large Spanish onion, was situated to the left of the vessel and rather forward; it was clearly sacciform, with a round, moderate-sized, neatly stamped out opening into the main vessel. (See Fig. 2.) The impression given was that a large patch of atheroma in the wall of the aorta had yielded, and that the tumor had formed itself by degrees in the depths of the adjacent tissues. The pouch was packed tight with stratified and adherent clots, pale and dense at the periphery but red and fresh at the center, that weighed 80 grams when extracted; it was evident that such an aneurysm could have no movements of expansion. At one point the wall between the pouch and the esophagus was so thin that when the clots were extracted light could be seen through it: it had been, however, protected by these layers of stratified clots. A second aneurysm, just across from the main one, had begun to form at the expense of another patch of atheroma. The left pneumogastric nerve was found running down over the larger aneurysm and closely adherent to its wall. A flat, calcified lymphnode was laid bare beneath the left bronchus.

In looking back over this case and endeavoring to account for its vicissitudes, we meet many obscurities. Two main suppositions are possible: (1) that the aneurysm was of ancient date, and that it was to it that the chronic pain of the preceding five years had been due; (2) that the long-standing pain was produced by chronic aortitis, and that the sudden, tearing sensation had been caused by the brusque giving way of one of the patches of atheroma. It is the second hypothesis that best satisfies the mind and explains the symptoms presented by the patient, and in particular the suddenness of the entire affair, and the acute suffering and obstruction. Histological sections of the periphery of the pouch showed, furthermore, that only a small portion was formed of arterial tissue, that in immediate connection with the edge of the opening in the vessel, the remainder consisting of connective tissue only; it was consequently a false aneurysm. The patient was unfortunately never questioned as to any possible antecedent syphilis. No explanation of the sudden appearance of this woman's idiosyncrasy for tobacco has occurred to us.

The violent atack of tachycardia was very likely due to some action of the tumor, pressure or inflammation, on the portion of the pneumogastric that was found in such intimate connection with its wall. What the patient described as her "swallowing in steps" was most probably caused by the dilated esophageal pouch emptying itself of its contents by successive efforts of contraction; but the overflowing of the bismuth from the supposed diverticulum into the esophagus through an opening high situated, was clearly a hallucination of the observer's mind. It is possible that the reason why the round shadow of the tumor was only seen at the last examination was that the latter had previously been completely masked by the heart, but that on account of its progressive extension into the loose tissues of the mediastinum it had finally worked itself out beyond the limits of the heart's shadow; at the same time it is not impossible that the reason why we saw the tumor at this séance and not at the others was that on this occasion we happened to examine from a more favorable point of incidence for the rays. The extreme thinness of the wall between the aneurysm and esophagus, noted at post-mortem, should be borne in mind by those who handle the esophagoscope; it is remarkable in our case that during the repeated maneuvers with this instrument and with catheters this wall did not give way, since it yielded almost at the first touch on actual manipulation.

Whether the uremic condition to which the patient succumbed was due to preexisting nephritis, or to the action of chloroform, we shall never know, as the renal tissues were already so decomposed when removed that sections were of no use although made. Certainly the patient had never shown signs of nephritis before or during her illness, and the numerous injections of morphine which her condition demanded had been followed by no ill effects.

This case again illustrates, finally, the difficulty physicians experience in changing their views, once the latter are firmly established. From the time that the initial stage of total uncertainty with this patient was replaced by an apparently positive diagnosis, that of diverticulum, everything was made to fall into line with that conception; although it is now evident that the absence of any high orifice, and the shadow behind the heart-apex, ought to have awakened serious misgivings in our minds, not to speak of the unlikelihood of any sudden appearance of acute symptoms in a congenital diverticulum at the age of fifty.

STRABISMUS IN INFANTS AND YOUNG CHILDREN.*

By ISAAC M. HELLER, M.D.,

NEW YORK,

ADJUNCT OPHTHALMOLOGIST, LARYNGOLOGIST, AND OTOLOGIST TO THE LEBANON HOSPITAL.

The strides of preventive medicine have been so rapid along those lines which concern the community that the individual has reason to feel slighted at his neglect. Strabismus has received little attention from the profession, which until recently has been content to stand idly by waiting for the child to outgrow his trouble, or after the damage has been done advises an operation, which at best can attain only a cosmetic result. It may be so because squint is an affliction rather than a disease.

In this day of keen commercial competition a cross-eyed young man is seriously handicapped in his efforts to gain a livelihood. Certain occupations which require accurate binocular vision, such as engineering of various sorts, in the army, navy, police and fire departments, and some mercantile lines, are shut out to him entirely, so that his range of usefulness is limited to a few vocations, for which he may be unfitted. This is not on account of his personal appearance alone, but, as will be shown later, because the squinting eye becomes almost blind, thus rendering its possessor as visually helpless as if he really had but one eye. A squinting young lady is almost as badly situated, for, while commercially the damage may be less, the deformity affects woman's most precious asset—her personal beauty. This might mean an actual interference with her opportunities of marriage and a consequent disappointment for life. The superstition surrounding "cross-eyed and wall-eyed" people, even in this enlightened age, is by no means a negligible quantity, and the number is not small who will have nothing to do with one so afflicted. It is apparent, then, that we have to deal with a factor of real economic importance to the individual who is entitled to a fair share of the practitioner's consideration.

Etiology.—Each mother gives a different reason why her child squints, and all the infantile diseases and accidents imaginable have at some time been blamed therefor. The usual story is that the infant was born with perfectly straight eyes, but that after some sickness, or sore eyes, or after the nurse held the baby in a peculiar position, or permitting the child to associate with and imitate others who were cross-eyed, besides other reasons too numerous to mention, it was noticed that the little one started to turn his eyes in, or, less often, outward.

Careful investigation shows there can be only a contributing factor in any of these reasons at most. What is nearer the truth is that the baby had a tendency to squint, or this was so occasional as to escape detection of those about him. Then his acute illness overtakes him and in his weakened condition he loses some of his strong muscular power, and this relaxation allows his squint to become apparent to his now watchful mother. It is surprising how marked a strabismus can be perfectly apparent to strangers and yet pass unnoticed by doting relatives. The exception to the above is diphtheria, which causes a true paralytic strabismus, but which rarely becomes permanent, and does not come under the consideration of comitant squint. Of the numberless theories offered there are but three worthy of serious consideration, viz., the short-muscle theory, the refraction theory, and the fusion theory.

1. The short-muscle theory: It seems most obvious to regard an internal strabismus as due to a short internus muscle or a divergent squint to an overacting externus. The equally obvious remedy then would be to cut that offending muscle. This theory is easily disproved by showing that each eye moves freely in all directions; that the squint may affect either eye alternately, and in the beginning is not infrequently occasional, and that during sleep or anesthesia, or after the instillation of atropine the eyes are frequently perfectly straight. It was formerly common practice to tenotomize these cases with many disappointing functional results.

2. Refraction theory: Donders was the first to call attention to the fact that convergent strabismus was usually accompanied by hyperopia alone or in combination with astigmatism. Worth found this true in 1,729 out of 2,337 cases, or over 74 per cent. The idea was as follows: A normal eye looking at an object twenty or more feet away uses none of its accommodation an dthe eyes are parallel. On looking at an object thirteen inches off, the average reading distance, he exerts three diopters of accommodation. Inasmuch as accommodation and convergence are inseparable, he must at the same time exert his interni to the equivalent of three diopters or three meter angles in order to bring his lines of vision together at the required point. A hyperope of say three diopters must use his accommodation just that much to see things at twenty feet and his eyes tend to converge even for distance. Now, when such a person wants to read ordinary print he also must accommodate three diopters, which, added to his three diopter handicap, means six diopters that he is now using. As stated, accommodation without convergence is impossible, hence his eyes turn to a point six meter angles or six and two-thirds inches off. The eyes pointing thus receive a very imperfect image of an object thirteen inches away, since the rays do not fall on the fovea directly. To correct this, the patient unconsciously rotates one eye (the better one) outward until the macula is reached. As you well know, the outward rotation of each eye is inseparably associated with the inward motion of the other. The result is an excess inward rotation of the squinting eye. The rays now fall on the fovea in the fixing eye and on the nasal side thereof in the squinting eye. Impressions recorded here are never clear and the child soon learns to ignore them completely. Where the vision of each eye is equal the strabismus alternates until one eye becomes fixed definitely. This theory held for a long time, although it failed to satisfy those cases where there was no refractive error and where internal strabismus was associated with myopia. Moreover, it did not explain that large number of hyperopes who show no tendency to squint whatever. For a time it was believed that an eye turned in or out because its congenital vision was so inferior to that of its fellow and its image so blurred that the eye deviated from the true line of vision the more easily to disregard his diplopia. This poor vision or amblyopia is now considered an effect rather than a cause of squint. That is a sort of atrophy of the rods and cones following disuse just as a limb atrophies in a cast after a fracture. Worth believes that a true congenital ambly-

*Read before the Medical Society of the Borough of The Bronx, April 12, 1911.

opia is extremely rare and that most cases so regarded are really due to undiscovered or neglected squint. In the thousands of cases that have come under his notice there are but twenty-three which he counts as truly congenital. In general it may be said that the earlier in a child's life a squint develops the greater is the chance of that eye becoming amblyopic.

3. The fusion theory: Claude Worth of London in 1903 wrote an excellent monograph on the etiology and pathology of squint, calling attention to a new factor. His list includes 2,337 cases of all varieties of strabismus, covering a period of ten years, of which 90 per cent. developed before the age of six. He shows that none of the preexisting theories accounts for all cases, so he looks about for one which does. Few of us with normal vision realize that we really see everything twice—that one distinct picture is projected on the retina of each eye. This you can readily prove to your own satisfaction by pressing gently on one eyeball and on looking at a light you will clearly see two. Each spot on the retina of one eye has its relative area on the retina of the other with the exception of the extreme nasal sides. All rays falling on these corelative points are perceived as one by the sense of fusion situated in the visual center of the brain. This fusion is very important, since it gives us our sense of proportion and perspective, without which all things would seem flat. Worth claims this fusion faculty is absent at birth and bases his conclusions on the following observations. He placed children a few hours old in a dark room and threw the image of a candle by means of a concave mirror into their eyes. The infants would fix the light for an instant and then turn away. This is probably a purely reflex act. At the end of two to three weeks the infants would fix the light steadily for several seconds at a time with one eye, but would not converge both visual axes. At five to six weeks, as a rule, the positions of the reflections were symmetrical on the cornea, showing a binocular fixation, but now and then one eye would deviate a little inward, or more rarely outward, while the other fixed the light. During these first few months of life the eye movements are uncertain, not completely controlled by the higher brain centers. At five to six months, however, the child's attention can be engaged by almost any bright object, while one may slip a 12-degree prism, base out, before one eye, which will rotate in, showing there is an effort made to maintain binocular vision. In other words, the vision of each eye is present at birth at the macular region. The convergence which tends to subserve binocular vision develops during the first few months so that it is evident by the seventh month and goes on to perfection up to the age of six years. During this period, should anything occur to interfere with this development, it is a question whether an effort be made to overcome it or whether the newly acquired art shall be abandoned and the vision of that eye suppressed. After the sixth year the fusion sense is fully developed and nothing can occur to destroy it save a true paralysis of one or more muscles. The commonest provocations contributing to the overflow of binocular fusion are the following: 1. Hyperopia, which has already been considered. 2. Anisometropia, that is where there is a marked difference in the refraction of the two eyes, such as one eye being normal and the other ten diopters myopic. 3. Hyperphoria, which is an imbalance of those muscles which raise and lower the eyes. 4. Esophoria and exophoria an imbalance of the lateral eye muscles. 5. Specific fevers. These children usually have considerable hyperopia and in their enfeebled condidition find accommodation, coupled with a poorly developed fusion sense, quite an effort. This upsets their unstable equilibrium and the squint becomes apparent. 6. Violent mental disturbance such as convulsions, severe fright, etc., may, in the absence of the fusion faculty, upset the equilibrium of the convergence center. One influential factor must not be overlooked—that of heredity. In a fair number of my cases there was a distinct history of strabismus in one or more members of the immediate family and Worth found it so in 52 per cent. where his information was reliable.

Symptoms and Course.—Usually in the beginning the squint is not constant but appears when the child is fatigued or toward evening. At the same time he may be restless and irritable or if old enough may complain of headache. This is due to the muscular effort endeavoring to maintain binocular vision. Later on it is noticed that the squint is present most of the time but alternates from one eye to the other. The child is now thought to be manipulating his eyes purposely and is frequently admonished for it. Soon, however, the squint becomes fixed in one eye and remains there permanently unless artificially relieved. No effort is made to secure binocular vision, consequently these patients are not particularly subject to headaches.

Diagnosis.—In well-developed cases the diagnosis is made at a glance though it may sometimes be difficult to determine which is the squinting eye. The simplest method is to take the child into a dark room and hold a lighted candle three feet from his eyes. He will immediately look at it and the reflections thereof will be plainly seen on each cornea. In the fixing eye it will be at the center, while in the squinting one it is far to one side. It is particularly in the undeveloped cases that considerable attention must be given to detect the slight changes of position and repeated observations made to come to a correct conclusion. In general it is a safe rule to follow that any child over six months who squints, even occasionally, should have atropine dropped into his eyes and his refraction carefully measured.

Treatment.—This is after all the most important part of this paper. Formerly nothing was done for these unfortunates until they were old enough to read. Now we realize a child is never too young to receive some treatment for his strabismus and it is just among infants that we can do the most good. We first test the vision of each eye separately after carefully binding up its mate. Then we use Worth's globes, which are no more than white marbles of five sizes ranging from ½ to 1½ inches in diameter. The largest ball is thrown on the floor with a twist so as to make it "break" its direction, then the next smaller, and so on until the smallest is reached. At the same time we must watch the direction of the child's eye to determine if he follows the ball. If he is old enough several are thrown together and he is asked to pick them up. By this means one can readily tell if the child has vision in each eye and approximately how much. The better eye is tested first so as to give him the benefit of the experience and the poorer eye compared with it. The refraction is then carefully determined by retinoscopy after the instillation of atropine and the results recorded. Infants under ten or twelve months

should now have a ¼ to ½ per cent. solution of atropine placed in the better eye daily to paralyze its accommodation and compel the use of the poorer one. Some oculists put the atropine in both eyes for quite a long time. This is a mistake, since the accommodation of both eyes is suppressed and there is no opportunity to exercise either. The object is to force the use of the steadily growing weaker eye and develop its function by exercise just as we endeavor to develop a weak part elsewhere in the body. It has been my practice, too, to order a pair of cheap, empty spectacle frames to be tied about the little one's head so as to make him familiar with the sensation of wearing something about his eyes and ears. After one year we order the proper glasses as we would for an adult. It is marvelous how naturally these little tots take to a well fitted pair of specs. My youngest case was eleven months and there is another of fifteen months. Both these children wear their correction constantly while awake and take them off only when the lenses are dirty, causing blurred vision. The eyes are quite straight with the glasses and evidently feel comfortable with them and seem lost without them. At first these patients will need watching that they do not pull the specs off and bend the frames, but a little patient training with a judicious slap on the hands now and then will do wonders. Even these cases should have a weak solution of atropine instilled into the stronger eye once daily for a month at a time to exercise the weaker one. The main objection to a baby's wearing glasses is that in falling he might break the lenses and the splinters injure his eyes. This danger is more fancied than real, because glasses properly made with secure rims do not splinter but crack, and personally I have never heard of an injury by this means. As soon as the patient is old enough to understand what is wanted he should be made to exercise his fusion with the amblyoscope of Worth. Starting with the simple figures he is taught to recognize two different but related objects simultaneously. For instance, the picture of a bird is put in one side of the scope and that of a cage on the other. By varying the intensity of the light behind the pictures he can be made conscious of both. He is then told to try to put the bird into the cage, which can readily be done by changing the distance of the arms. Weekly exercises of this sort, gradually increasing the complexity of the figures, train the fusion sense and binocular vision to a degree hitherto unhoped for. It goes without saying that these children require constant attention and periodic supervision, but the prize is well worth the effort.

This plan of treatment conscientiously pursued will at least preserve the sight of the squinting eye even if it does not overcome the strabismus and secure binocular vision. Now, if after all this the child reaches the age of seven or eight years and still squints then an operation to straighten the eyes will be indicated and if successful will result in two useful eyes. It will be found, however, that where these means have been thoroughly tried out the cases requiring later operation will become progressively fewer. The difficulty lies partly with the physician who believes that the child will outgrow his strabismus and partly with the misguided mother who, only too willing to coincide with him, hates to have her "darling's beauty marred" with glasses, little realizing that the squint is far more of a deformity than a pair of well fitted specs. It must be clearly understood that they rarely outgrow their affliction and when they do one eye is badly damaged. It is a plea for a square deal for the little "cock-eyed kid" who is to be the butt of his playmates' jokes and later in life heavily handicapped in this already sufficiently close race for existence that I would ask you not to neglect these cases but do something as soon as you discover them.

450 Tremont Avenue, East.

REPORT OF CASES.

By J. P. KENNEDY, M.D.,

WINGHAM, ONTARIO.

SURGEON TO THE WINGHAM GENERAL HOSPITAL.

In the preface of his recent work, entitled "One Hundred Surgical Problems," Mumford says: "The teachings of practice are conveyed by example as well as by precept. Until recent years writers knew and availed themselves of this fact. They set forth their lessons by case illustrations. Galen did this; so did Paré, that master of the method; so did Wiseman and Le Dran, Hunter and Petit, Cooper and Paget. The method in proper hands is luminous, and the lessons are instantly comprehensible. We abused and nearly lost that method with the development of the statistical, analytical practice of the last century." The report of our successful cases is naturally more agreeable than the report of our failures, but the latter may be more instructive and interesting.

I have before me notes of three cases which died shortly after operation, not perhaps through any fault of technique, but in one of the cases, at least, because the operation was not submitted to sooner, although the patient had been warned six years before that she should be operated upon. One of the other two cases had never consulted a physician in regard to her condition until the day before the operation was undertaken, and the condition had insidiously become so far advanced that it was beyond the aid of surgery.

Case I.—Mrs. S. was referred to me by Dr. Gordon of Lucknow on March 21, 1910. Age 43 years. Housewife. Family history: Father living and well, age 85. Mother dead at 74 from "knotting of the bowels." Brothers, one dead, age 34, from epilepsy. Six brothers living and well. One sister living and well. No history of tuberculosis, malignancy, heart, kidney, or mental disease in family. Personal history: Patient began to menstruate at 14. Painful, regular, lasted three days, the last period three weeks ago.

Marital history: Married at 24 years of age. Never pregnant. Husband living and healthy. Previous illnesses: Always strong and healthy until present illness. About January, 1909, began to get bloated after meals, had to unfasten dress to get relief. Took soda with relief, but always felt tired. In April caught a cold, and had severe pains in the knees and across the back for about one month, but still did work. Felt weak all summer. In August pain in the stomach became worse. Was troubled with gas after meals; this was followed by vomiting of watery material. Consulted Dr. Spence of Lucknow and was under his treatment until March, 1910. Stomach improved, but about the middle of February began to have smarting pains just after urinating. Then noticed that she did not urinate so often during the day. Always

urinated two or three times during the night. Says quantity was less than usual, but never had suppression. Had been constipated since summer of 1909. For past month has had crampy pains all through bowels, especially when bowels moved. During the same time has noticed blood and matter in the stools, that is, she says, "streaks of blood."

She now came under the care of Dr. D. M. Gordon of Lucknow, who referred her to me. Upon examination I found a small slight woman with rather an anemic appearance, weighing possibly 115 or 120 pounds. The principal thing she complained of was pains and distress across the abdomen, loss of appetite, general weakness, and malaise. Upon examining her I found the abdomen very much distended and fluctuating. The examination of the blood showed hemoglobin, 80 per cent.; erythrocytes, 4,600,000; and leucocytes, 15,000. Her heart and chest were negative. I was inclined to think her condition was tubercular peritonitis. She positively refused to permit me to make any vaginal examination, but permitted my assistant, Dr. Margaret Calder, to make a rather unsatisfactory one. Dr. Calder told me that she was sure there was at least a small lump in the pelvis, which I concluded might be due to tuberculous tubes. Urinary analysis was negative. On April 5, in the Wingham General Hospital, I opened the abdomen. At once a large amount of turbid fluid escaped, of a slightly bloody color. On exploring the abdomen I found nothing abnormal until I reached the pelvis, when I came in contact with a mass about the size of a cantaloupe. This I brought up and found it to be a cyst of the left ovary. I transfixed the broad ligament, removed it, and closed the abdomen. On the third night after the operation I was hurriedly summoned to the hospital because the nurse told me that the dressings were all saturated with blood. When I arrived at the hospital I found that the lips of the wound had slightly separated, and what the nurses supposed to be blood was merely the escape of some blood-tinged fluid from the abdomen. Mrs. S. gradually sank and died April 12, one week after operation. The tumor itself, as I have said, was about the size of a cantaloupe. It was filled with fluid. The pathological examination of the specimen, made by Professor McKenzie of Chicago, showed it to be a large round celled sarcoma. I cannot see how this woman's life could have been saved, as at no time in the history of her case would she submit to a proper vaginal examination.

Case II.—This was referred to me by Dr. Chambers of Tiverton, with the following history. Mrs. M. Age 51 years. Family history: Mother living and well. Father dead, cause unknown. Husband died at 40 from tuberculosis. One daughter died at 18 from tuberculosis. A son and daughter living. Personal history: Mrs. M. was a tall angular woman, who had apparently had a rugged constitution. She was quite bright and alert mentally. Had always lived on the farm. Worked hard, and had been healthy until about one year ago, when she began to feel tired upon exertion. Lost in flesh. Had a great deal of "gas in the stomach," and coughed up a good deal of "phlegm" during the year. Did all her own work, however, until March, 1911. At this time she began to vomit this "phlegm," and thought food did not agree with her. She also noticed in April that she began to get "bloated." This had steadily increased and since then she became thinner about the face, neck and thorax, and noticed shortness of breath. She was not constipated and menstruated regularly, last in February. The "bloating," as she expressed it, kept increasing. On June 27 Dr. Chambers was called in to see her and found her with an enormously enlarged abdomen, which fluctuated on percussion. He suspected ascites, and aspirated, but to his surprise nothing came through the trocar. He told her that she might possibly have some malignant trouble. He then advised that she consult a surgeon, and very kindly brought her over to the hospital the same afternoon in his automobile. Upon examination I could not make a positive diagnosis, but as she had been a very robust, strong woman and was yet apparently in very fair condition, I determined to make an exploratory incision. This I did at the hospital the following morning. Upon opening the abdomen I found it filled with a jelly-like substance, which I could scoop up in handfuls. I concluded at once that I had a malignant disease, probably colloid cancer, and after taking out two or three basins full to give her relief in breathing, closed the abdomen. The wound healed by primary union, and she was able to go home July 15, but died from exhaustion the following day. The pathological examination of this substance was made by Professor Duncan McKenzie of Chicago, who pronounced it a large, round-celled sarcoma of the omentum and peritoneum. Perhaps in this case it might have been better not to have operated, but I took the chance of the possibility of it being a large multilocular cyst, and I do not know that the operation hastened her death. It certainly relieved her breathing and made her easier for a week or ten days.

Case III.—This case was referred to me by my assistant, Dr. M. C. Calder. Mrs. J. was examined by us at our offices on January 10, 1911. Her appearance was tall, spare, and anemic. I had known Mrs. J. by sight for the past 17 or 18 years, and she always had an anxious anemic facies. Family history: Father died at 51 years of age from cancer of the stomach. Mother living and well. One sister died some time after an operation for pelvic tumor, which was said to be malignant. Personal history: Patient's age 39 years. Her menstrual history has always been normal, periods painless, and regular every 28 days. Has been married 18 years. Three children, youngest seven years of age. No miscarriages. After the birth of her youngest child she did not regain her strength quickly and consulted her physician here, who made a vaginal examination. She was told at this time that she had a tumor on the left side of the pelvis, and was advised to have an operation. Shortly after this she consulted a surgeon in Toronto, who confirmed the diagnosis, and also advised an operation. For the last three months the tumor, she said, had been growing rapidly, otherwise she felt fairly well, although more easily tired than formerly. She mentioned especially that she had noticed the enlargement increasing very rapidly during the past six weeks. Upon examination found a large fluctuating abdominal tumor. Heart and chest normal. Temperature normal. Her blood examination at this time showed hemoglobin, 70 per cent.; erythrocytes, 5,000,000; leucocytes, 9,200.

Diagnosis: Ovarian cyst. Advised operation. She entered the hospital January 22, 1911. I opened the abdomen the following morning. Found

no free fluid in the abdominal cavity and removed what appeared to me to be an ordinary multilocular ovarian cyst. Stitches removed on the seventh day after operation. The wound was apparently healed. The following day, however, it was noticed there had been quite a considerable oozing of blood on the dressings from the upper part of the wound. This subsided in a day or two, when there appeared a nodule along the right side of the wound. After the bleeding in the line of the wound and the formation of the nodule I became suspicious of malignancy and had a portion of tumor sent to Professor Duncan McKenzie of Chicago for a pathological examination. His report is as follows: "I failed to find any evidence of sarcoma. It is not sarcomatous, neither it is carcinomatous, nor tuberculous. It shows every evidence of long standing. I will send you the slides and you will find that it is benign cystadenoma." She left the hospital February 12. After returning home she seemed to gain in strength. For a time she was able to perform her household duties, and to go about town. She gradually began to feel her strength failing toward the latter part of May. She came back and consulted us on June 15. Upon examination we found that the nodule along the abdominal wound had increased considerably in size, to about that of a walnut. Upon vaginal examination I discovered another pelvic tumor somewhat larger than a grape fruit. She complained of stinging pain in the abdominal nodule and also a good deal of pain in the left hip, which ran down the leg and resembled sciatica. I thought possibly this was due to the pressure of the pelvic tumor. Having sent only part of the specimen to Professor McKenzie for examination, I thought possibly that I had selected a part not malignant, and decided to send the entire specimen to Dr. O. R. Mabee, pathologist, Toronto General Hospital, for a complete examination. I received the following report from him July 7. "Microscopic examination shows the condition to be a papillary cystadenoma of the ovary. In reference to the malignancy of the condition I may say that if they are entirely encapsulated and have not ruptured, or are not ruptured in taking out, they do not recur. If, however, the contents and cells come in contact with the peritoneum, secondaries develop on the peritoneum, or in the wound, by direct transplantation. It would seem to me that this had occurred in your case. The condition, however, is never extremely malignant. We had a case recently who lived five years with the secondaries on the peritoneum. If you wish to be absolutely sure, it would be best to excise the nodule in the wound." After getting Dr. Mabee's report I recommended that she submit to further operation. This she delayed until July 25, when I again opened the abdomen and removed an ovarian cyst of the right ovary, about the size already described. I also removed a nodule attached to the line of old incision and also to the omentum. Professor McKenzie examined both tumor and nodule and pronounced them both papillary cystadenomata. Her convalescence after this operation was somewhat delayed. She left the hospital, however, on August 15. She now suffered a great deal of abdominal pain. Tumors gradually appeared all over the abdomen. The inguinal glands on both sides were enlarged. Several nodules formed in the popliteal space and quite a large one in the calf of the left leg. She lost appetite, wasted rapidly, and died from exhaustion on September 26. In my opinion this is a case in which delayed operation caused death. Undoubtedly if this patient had submitted to operation six years ago she would still be alive and well.

A cystadenoma may not be malignant at times, but it certainly appeared to be so in this case. Kelly and Noble (vol. 1, page 190) say: "Often it is impossible to determine from a pathological anatomy whether the tumor is benign or malignant." "The papillary growths in the interior of the cysts may break through the wall and appear on the peritoneal surface of the tumor, or primary papillary masses may develop in this region. Inoculation growths upon the omentum and general peritoneum are very frequent; the growths may disappear spontaneously after removal of the primary lesion, but often remain and pursue a semimalignant course." "Distant metastases occasionally develop, but are rare." Delafield and Prudden, in the last edition of their "Pathology" (page 834), say: "The papillary outgrowths (of the cystadenoma) often break through the cyst walls and may be transplanted to the peritoneal or other surface in the form of multiple cystic or papillary tumors." Whether this happened just previously to my first operation, I cannot say. However, I was careful to avoid, as far as possible, allowing any of the fluid contents of the cyst to get into the abdominal cavity or against the edges of the wound, but I may have failed. In the second operation the cyst was so tightly embedded in the pelvis that I found it impossible to dislodge it without breaking it. Needless to say that in all three cases the surgeon was censured by the laity for not saving the patient's life.

THE REAL VALUE OF CARBOHYDRATE FEEDING IN TYPHOID FEVER.

By E. R. GARDNER, M.D.,

PITTSBURGH, PA.

VOLUMES have been written on typhoid fever, its symptomatology and treatment, and it is not my purpose to burden the reader with a résumé of the many different treatments that have gone before, but to offer for consideration a method of treatment developed along the lines of bacteriological investigations in which an attempt has been made actually to combat the invading organisms themselves. Dr. Theobald Smith, in his paper entitled "Certain Aspects in the Life History of Pathogenic Microorganisms," has put it clearly when he says "It is what bacteria do, rather than what they are, that commands our attention since our interest centers in the host, rather than in the parasite." In typhoid fever we have a bacillary infection and invasion with lesions referable primarily to the intestinal tract. We are dealing furthermore with a self-limited disease presenting a symptom-complex with one characteristic feature common to all, namely that of a long-drawn-out battle between the host and the disease. But this is not to imply that we are not able to modify the severity of the symptoms and thereby gain much in comfort to the patient. On the contrary it is a notable fact that in recent years there has been a decided fall in the mortality, brought about no doubt by a more intimate knowledge of the disease and the application of modern laboratory and clinical findings. Through the activities of the trained worker in the laboratory the true pathology of the disease was

brought to light, and this, together with our added knowledge of the functions of metabolism in health and disease, has wrought a great change in the treatment of typhoid fever. In the light of our present-day conception of typhoid fever we are made aware of the fact that the internal antiseptic form of treatment is based on an erroneous conception of the disease.

Drugs to be of any value in the modern scientific sense must influence the infection directly or indirectly. Antiseptics of all known kinds are practically worthless in the treatment of bacterial infections; indeed, according to many good observers they may even seem to favor rather than retard the bacterial growth and in many cases interfere with digestion. Friedenwald and Leitz in their experiments on the bactericidal properties of intestinal antiseptics have arrived at these conclusions: (1) That most intestinal antiseptics markedly interfere with gastric digestion. (2) That this disturbance varies largely with the nature of the gastric secretion and the motility of the stomach. (3) That salol, salicylates, and lactobacilline are the least harmful to the gastric digestion; that betanaphthol, aspirin, ichthalbin, thymol, salicylic acid, and creosote are most apt to interfere with gastric digestion.

It would appear then that the administration of intestinal antiseptics in the treatment of typhoid fever is purely empirical and of no avail in influencing the course of the disease. The course of treatment usually followed is supportive and symptomatic, with much careful nursing and relying on nature to bring the case to a successful termination. In the absence of any specific therapy what shall constitute our treatment of typhoid fever? It is known that in all fevers the body requires as much energy and heat as at rest in health, and in typhoid fever at least 25 per cent. more is required to meet the increased loss due to febrile heat production. We should not starve our patients, for starvation in itself is a disease. The loss in body nitrogen during fever is due to (1) starvation, (2) the fever itself, and (3) toxic destruction.

The wasting in typhoid is usually marked, and this loss can be avoided to a greater or lesser degree by food. One would naturally turn to proteins to make good this loss of nitrogen, but it has been proven that sufficient amounts to meet the daily needs are all that is required. Seventy grams of protein is sufficient for daily body needs, and any excess must be destroyed and eliminated which adds an extra burden to the already weakened organism. Fats are of high caloric value but on account of their tendency to disturb digestion and produce diarrhea should be used with caution. Carbohydrates are known to protect body nitrogen better than any other food; again the absorption of fat and protein in typhoid fever is 10 to 15 per cent. below normal, but Folin has shown that the absorption of carbohydrates in this disease is practically normal. In the selection of a diet no hard and fast rules can be laid down, for all patients cannot be freely fed, but a dietary of easily assimilable foods would be sufficient for all ordinary cases.

Lactose is the carbohydrate of choice for the following reasons: (1) It is the natural sugar of the mammalia—man, dogs, and herbivorous animals. (2) Its caloric value as a food is high. (3) It is a powerful diuretic, without any deleterious effect on the kidneys. (4) It protects the body nitrogen, and the nitrogen of the food. (5) It is not bulky, does not produce nausea, and does not ferment easily. (6) It prevents bacterial decomposition of protein by changing the character of the bacteria of the intestinal tract from the putrefactive to the fermentative type. (7) It is easily assimilated.

Supportive measures by the administration of food sufficiently high in caloric value to supply the dynamic needs of the body would seem to be the logical method to pursue, and in this diet can we not include a food yielding a goodly number of calories and at the same time modify the intestinal organisms, and change the type of bacterial activity? Escherich, in 1886, noticed a decided increase in the number of liquefying bacteria in the feces of dogs fed on a purely protein diet.

Metchnikoff was the first to attempt to change the intestinal flora by alterations in diet, but he along with Tissier, Moro, Finkelstein, and others did not recognize the importance of the study of the biology and chemistry of the intestinal flora, and therefore failed to appreciate the fact that the diet of the patient exercises a marked influence on the character of the metabolism of the organisms in his intestinal tract. Dr. A. I. Kendall, of Boston, in his study of the biochemistry of the intestinal flora in bacillary dysentery has shown that if there are incorporated in the diet of the patient utilizable carbohydrates, the organisms will attack the sugar in preference to the protein, and if there is an excess of sugar so that the bacilli form acid (*B. Typhosus* has the capacity to form acid from sugar) very little toxin is produced.

From the work of Kendall may be drawn these conclusions: (1) Most bacteria in the presence of carbohydrate utilize carbohydrate in preference to protein. (2) The bacterial toxins so far as is known are associated with the breakdown of protein, and sugar appears to prevent their formation in appreciable amounts. (3) Expressed thus, fermentation (the hydrolysis of carbohydrates) takes precedence over putrefaction (the breakdown of protein).

In dysentery, as in acute infectious diseases, there is during the acute stage a great loss of body nitrogen, a loss far greater than can be accounted for by simple starvation, and the term toxic loss of nitrogen has been used by many observers to express this condition. According to Kendall toxic loss is due to the action of bacterial toxins which are absorbed. The initial damage cannot be undone, but it appears to be possible to prevent in part at least further insult in this direction by applying the principles stated above; namely, by adding sugar to the diet of the patient. The sugar serves a two-fold purpose: (1) The character of the bacteria of the intestinal tract is changed from the putrefactive to the fermentative type. (2) The patient is provided with the food high in caloric value and most easily assimilated.

Lactose is used because it is broken down, according to physiologists, in the intestinal wall so that the sugar is broken up just where the lesions are to be found. This breakdown of the sugar provides dextrose, which is utilized by the *B. dysenteriæ*, thus shielding the nitrogen of the body and probably tending to arrest the further erosion of the mucosa as well as to prevent further toxin formation.

In typhoid fever, in which, as in bacilliary dysentery, the etiological agent is of exogenous origin and where the primary lesion is in the intestinal tract, why could not the same principle be applied as in dysentery, since the conditions are similar?

It would appear rational to add lactose to the diet of typhoid fever patients to protect the body nitrogen, rather than to feed a diet potentially purely protein, in order to change the character and metabolism concerned in the morbid process and to provide an easily assimilable food. Kendall even hints that the toxin formation of typhoid bacilli which have penetrated the body may be influenced by keeping the dextrose content of the blood up to the usual limit, and the lactose may be fed with this end in view.

Lactose has been used extensively by a number of clinicians in the dietary of typhoid fever patients, chiefly for the high caloric value it contained, but the real value underlying the use of lactose (or of any sugar for that matter) is not simply a matter of feeding calories which made the use of sugar so valuable, but the prevention of toxin formation. The practical application of the foregoing statements has been made in only one case of typhoid fever,* but it seems to me that enough has been proven by the results obtained to justify a continuance of the treatment.

The patient, a young man, 18 years of age, was seen one week after his illness began; he had a temperature of 103°, and exhibited the clinical symptoms of typhoid fever; he was put to bed, and a Widal test proved positive. The treatment used was a carefully regulated diet (including a carbohydrate) and taking into account the caloric value of the foods used. No attempt will be made to give the chemical composition and caloric value of food; they may be found in Atwater's table. Bulletin No. 21, U. S. Department of Agriculture. Feeding hours were 7 and 10 A. M., and 1, 4, 7, and 10 P. M. There were no night feedings unless the patient was awake, when the milk mixture described below was given. A milk mixture containing 7 ounces of milk, 1 ounce of cream, and 1 ounce of sugar of milk was administered every three hours during the entire course of the fever.

With the above mixture the nurse was allowed according to the wishes of the patient to feed any of the following foods: One soft boiled egg, soft toast (without crust) and butter, or stale bread and butter, tomato or bean soup (strained, 8 ounces); beef, lamb, and chicken broth (8 ounces) thickened with powdered rice (Q. S.); oatmeal gruel (strained) containing the white of one egg (5 ounces), cocoa, cup custard, and ice cream. Large amounts of cool water were given the patient daily, as was lemon albumin and lemonade, and in fact he was urged to consume large quantities of water. Water is an essential element of food, and it is undoubtedly true that it increases the digestion and absorption of food. Possibly the greatest benefit derived from the taking of large amounts of water is the stimulation of all the excretions, whereby the toxins are eliminated. When the water is given cold in large amounts it has the properties of an antipyretic, and obviates the necessity of frequent baths.

The benefits which seemed to follow this form of treatment were briefly: The absence of the typical typhoid facies, a good appetite, markedly less toxemia, nervousness, and mental depression. There was no extreme emaciation; the stools were formed and well digested. There was a rapid return to normal health and good general condition.

513 Empire Building.

*Since this paper was written four other cases have been treated along these lines with the same result as the case described above.

A CONVENIENT INSTRUMENT FOR READY CLINICAL INVESTIGATION OF THE SENSIBILITY TO COOLNESS AND WARMTH.

By TOM A. WILLIAMS, M.B., C.M., Edin.,

WASHINGTON, D. C.

When the spinal column is injured, it becomes of great importance to the surgeon to know whether a consequent paralysis or loss of sensibility arises from damage to the cord itself or implication of the roots or of a plexus in the vicinity. Since the researches of Head and Sherren,[1] and Head and Thompson,[2] the means for making this distinction are clinically available. It will be recalled that stimuli, as they pass from periphery to central end organ, are grouped in quite a different way in the peripheral nerves to the manner in which they are collected in the spinal cord. Thus, it has long been known that in the latter all the impulses of painful sensations run together in the heterolateral Gowers' tract, and that a lesion which interferes with any kind of pain always interfers with all kinds of pain. As is well known, the sensibility to cold and heat is conducted along the same tract as that of pain, although not in the same fibers; for one may be lost without the other, and either or both may be lost while the sensibility to pain is intact, and vice versa, although any of these combinations is rare, on account of the close proximity and interlacement of the conducting paths. Again, the knowledge of the attitude of our limbs is derived from impulses which mount the cord in the homolateral dorsal column, and they are there accompanied by fibers which make possible our appreciation of the locality of touch and of the distinguishing of the simultaneous touch of two points, at a distance from one another which varies on different parts of the body.

On the other hand, this latter test is the most convenient for determining whether a lesion is in the cord or in the periphery; for in the latter case, the loss of spacing sense is always accompanied by a proportionate loss of the superficial sensibility for distinguishing light touches and appreciating coolness and warmth, that is, temperatures between about 20° C and 40° C. In a lesion of the cord, however, there may be a loss of spacing sense without the least incapacity to appreciate either heat or cold and without loss of feeling to the lightest touches with cotton wool; but there is then always a concomitant loss of the sense of attitudes. In the lower limbs the compass test is not of great applicability, for the circle of discrimination is very wide, and people are not accustomed to this type of discrimination. The hairiness of the lower limbs, moreover, vitiates the testing of fine touch with cotton wool, for the order of sensibility excited by the stimulation of a hair is different from the "epicritic" (as Head has called it) resident in smooth skin. Hence, to distinguish between peripheral lesions and those of the cord clinical practicability requires the use of a different quantitative test; and it is for convenience in making this that I have devised the instrument now presented.

For estimating degrees of sensibility to temperature, Head had used silver test tubes containing water at a temperature ascertained by a thermometer placed in the tube. Now, silver tubes are expensive, and the insertion of a thermometer is inconvenient. Besides, in a small tube the loss of

temperature is rapid. So, in my instrument, copper is used, for it is nearly as good a conductor and much less expensive. It is used in a block, and not as a tube, again saving expense. The thermometer is firmly attached to the instrument, which greatly adds to its convenience; and lastly, rapid loss of heat is compensated for very simply; for the desired temperature is reached by plunging the base of the instrument into water in a large vessel, the total body of which retains its temperature much longer than does an instrument of any practicable size unless electrically heated as in the instrument recently devised by Mills,[3] the expense of which precludes its general use.

The apparatus consists of a cube of cast copper, 3 x 3 x 3 centimeters tunnelled out in the center to within two millimeters of the opposite surface. Into the tunnel is inserted the bulb of a thermometer of the kind used in storage warehouses. It registers from 10° to 140° Fahr. This thermometer has been selected only for its availability, for the range of temperature need not be so great, but it is a safeguard against breakage. The whole is mounted upon a wooden holder along a groove in which the thermometer is embeded for protection. The scale is easy to read as it lies in the furrow. For convenience of manufacture, the copper block is made in two equal parts, furrowed in such a way that the approximation of the grooves forms a circular tunnel for the thermometer. The two halves are clamped together with four copper screws; and the whole is in turn screwed to a strip of brass 3 mm. thick and 3 cm. wide. The brass fits along a bevelled out surface of the block, which extends to within 2 mm. of the foot. The brass strip is screwed also into the wooden handle which carries the thermometer scale, thus making the whole solid and giving a uniform surface of copper to place against the skin of the patient.

To use the instrument it is plunged into a large jug of water at a temperature approximating to that desired, say 25° C. when testing for appreciation of coolness, or 40° C. when testing the appreciation of warmth. It is very easy by adding cold water or hot water to obtain any temperature desired in the large vessel; and this will remain practically constant long enough to enable a series of observations to be taken sufficiently complete for current clinical use. Of course, it is easier to obtain accurate results when two instruments are used, one cool, the other warm; for it is then more easy to control the tendency of patients to continue to call all temperature stimuli by the name they used for the first stimulus felt. Any indifferent metallic substance may, however, be employed satisfactorily to eliminate this fallacy.

In thus aiding the clinician to diagnose between injuries and diseases of roots, central nervous systems, and peripheral nerves, of course, the instrument does not pretend to be a substitute for clinical acumen; no apparatus can do that; but it is a convenience, and furthermore affords a ready means for ascertaining data for purposes of comparison with the cases of other observers. It is thus useful both in the practice of medical, and especially surgical, art and in the compilation of the records which further the advancement of science.

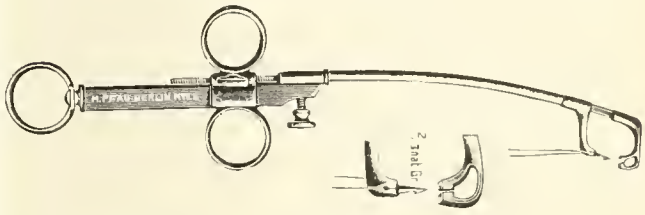
The Value of the Epiglottic Suture in Direct Laryngoscopy.—The following is the substance of a paper read by Cyril Horsford, M.D., F.R.C.S., of London, at the Fifth International Rhino-Laryngological Congress held in September last at Berlin.

The object of the communication was to draw the attention of laryngologists to the fact that the field of vision obtained by indirect laryngoscopy can be greatly improved by the passage of a suture through the epiglottis, and that this suture can now be rapidly and safely passed. He recommends the suture as a substitute more efficient in all respects than the many forms of epiglottis lifters introduced to facilitate intralaryngeal inspection. He further finds it frequently more acceptable than the direct method, especially for the removal of a growth situated near the anterior commissure. He has practised the method in a large number of cases since July, 1906, when the idea first occurred to him. References are given to the work of others in this field of enquiry (Türck, Jurasz, Semon, Gleitsmann). He has devised several instruments for the purpose, but the latest, the epiglottis suture forceps No. 2 (see illustration), made by H. Pfau, of Berlin, and Mayer & Meltzer, of London, is the most efficient.

"Its successful use depends, as in other intralaryngeal operations, upon the efficient preparation of the patient by local anæthesia. The needle is first threaded with a long piece of silk and the whole carefully streilized. With the aid of a laryngeal



mirror the suture is passed through the epiglottis and the ends brought over the center of the tongue and gripped by a pair of large artery forceps, which are then allowed to hang a little distance below the jaw. The tongue is then held for examination in the usual way, and it will be seen that the epiglottis is held up against the root of the tongue by the weight of the forceps only, and the intralaryngeal view greatly improved. The suture can thus be rapidly, easily, and safely passed. It causes no discomfort to the patient, occupies no space in the mouth, and it does not require the assistance of a third hand. It further helps to steady the larynx and increases the intralaryngeal illumination."

The author referred in his article to a case in which by this means he had succeeded at his first visit in removing a small fibroma from the vocal cord of a singer which had resisted numerous attempts at removal by the indirect and direct methods in other hands.

Significance of Pavor Nocturnus.—G. P. Boncour states that night terrors are a symptom indicative of an increased irritability of the nerve centers, and may be due to the most varied causes, including tuberculous meningitis. Sometimes pavor nocturnus is an isolated clinical picture, in which case it is associated with restlessness and psychomotor incoordination. Mental hygiene is, Boncour says, the chief therapeutic measure—*Progrès Médicale.*

PHYSICAL MANIFESTATIONS OF EMOTION.

IT is reported that a girl of eighteen, who had previously suffered a gastric affection, became jaundiced twenty-four hours after seeing a woman knocked down by a tramcar. Such cases of emotional icterus are not rare. One was cited by Oliver Wendell Holmes: "I remember a young wife who had to part from her husband for a while. She did not write a mournful pæan; indeed, she was a silent person and hardly said a word about it; but she quietly turned of a deep orange color with jaundice."

The influence of the emotions upon the bodily functions is oftentimes potent; and its possibility should never be disregarded. It is routine work for the practitioner to elicit a well-defined train of symptoms with a number of physical signs, and upon this anamnesis to make a diagnosis. But it is oftentimes as essential to the happy issue of a case to discover psychic factors which, though they have not been directly causative of a lesion, may nevertheless have contributed to its development. The latter procedure is the more difficult; because thought not being a tangible factor, we cannot accurately estimate to what extent it may influence the making of a blood cell, the production of lymph, the cardiac pulse rate, the digestion of food, the secretions (as of bile), and the like. But that thought does constantly influence such functional processes in the economy no one can doubt. "Mind healers" and all that kind of people would persuade the laity that their "mind cures" (which so often, in their inexperienced hands, intensify mental aberrations), are a twentieth century revelation. But recognition of the fact that the mind can be either salutary or baneful in its influence upon the bodily functions is abundant in literature, ancient, medieval, and modern. To instance only Plato: "Physicians cure the body with the mind; and the mind which is or has been sick can cure nothing."

It is a very old truism that thought strongly directed to any part of the body tends to increase its vascularity (its blood supply), and hence its tendency to inflammation. John Hunter's experience with Mesmer is classic: "I was asked to go to be mesmerized; but first refused because the spasm on my vital parts was very likely to be brought on by a state of mind anxious about any event; and I feared lest it should be imputed to animal magnetism. But considering that, if any person was afflicted by it, it must be by the imagination being worked up by the attention to the part expected to be affected, and thinking I could counteract this, I went; and accordingly when I went I was convinced by the apparatus that everything was calculated to affect the imagination. When the magnetizer began his operations, and informed me that I should feel it first at the roots of the nails of that hand nearest the apparatus, I fixed my attention on my great toe, where I was wishing to have a fit of the gout; and I am confident that I can fix my attention to any part until I have a sensation in that part. Whenever I found myself attending to his tricks I fell to work with my great toe, working it about, etc., by which means I prevented it having any effect upon me."

Tuke made a memorable division of mind into intellect, will, and the emotions. The intellect and the will are mostly concerned with the cerebrospinal portion of the psychic machinery—that portion which contains (in the cerebrum) the higher centers—those centers which under normal conditions dominate the body. The growth of these centers is coordinate with the race; they represent the latest development in the evolution of living creatures. They are concerned with speech, memory, ideation, judgment, reason, and the like. It is these centers which under abnormal conditions (such as profound shock or tremendous emotional stress) are held in abeyance and put temporarily out of action. The emotions react mainly upon the ganglia of the sympathetic system, which are mostly in the thorax and the abdomen; the fibers from these ganglia control largely the involuntary functions of the various organs in those cavities—the liver, the heart, the lungs, and the like. Thus are such emotions as grief, joy, terror, anguish, anger, love, hatred, oftentimes mirrored in the flesh. It is repeatedly observed how powerful emotions excite or depress the action of sympathetic ganglia, and through their filaments effect changes in excretion, secretion, and other important functions. Violent emotions modify nutrition; diseases growing out of perverted or defective nutrition may well have originated in acute shock more or less profound, in chronic shock, or in other emotional disturbance. And the possibility of such cause and effect should ever be taken into consideration in practice.

ALCOHOL A DEPRESSANT.

THE fact that alcohol is in large doses physiologically a depressant, so often ignored by the public and by their preceptors, the physicians, as well, acquires additional importance from the circumstance that the majority of men and women will not do to excess what they know is harmful to them. Great is the evil that has come to the human race through the misuse of the term stimulant for depressant. If it is the duty of the medical man to teach his public that the familiar house-fly is a "typhoid fly," surely it is his duty to instruct his public that alcohol is a depressant, "crushing," and "subduing" rather than a stimulant "goading on" to increased activity—asthenic and almost never sthenic. The

immeasurable misery caused by alcohol in this world of ours, as is generally recognized, lies largely in two of the circumstances related to alcohol: one of these is that the drug is a sedative and financially, as well as otherwise, a very expensive one; the other one is that habituation to its use is both easy and enslaving. Let us see then how it is a depressant in each essential phase of its physiological working.

In metabolism it acts always, even in small amounts, to lower the body temperature, and in quantity it cools the tissue-protoplasm beyond recovery. The sense of body heat, of course, arises almost wholly in the skin and alcohol raises the surface temperature by a marked vasodilatation. This effect far outbalances whatever increase of heat-production comes from its endogenous combustion. Herein is the most essential of all possible modes of depression. Despite the fact that in amounts of not over 50 or 60 c.c. daily alcohol is oxidized largely in the musculature, the action of the muscles is disorganized and rendered less powerful as well as far less efficient. The apparent stimulation of the heart in rate and vigor, recent physiology construes as in reality a depression of the vagal influence over the ventricles —two negatives thus making a positive. But even so, the rest-periods of the organ are shortened materially, its total strength being therefore literally depressed in a period which is long enough to involve fatigue.

Respiration is markedly affected by large doses of alcohol, the medullary centers being apparently directly depressed by the poison in the blood. Digestion is checked by alcohol in large amount, the action being local on the mucosa as well as reflex and sympathetic. The nervous system is typically depressed by alcohol, as one may often see in the immunity of intoxicated persons to falls and blows upon the head and other seats of nerve-masses. Mental action, too, is depressed in nearly every case with the exception of the imagination and certain phases of emotional activity of less efficiency and value than the intellectual faculties. The depression exerted on the all-important chromaffin and thyroidean system by alcohol may be presumed from their close dependence on normal metabolic conditions, but the action of alcohol in this respect remains to be worked out. The "stimulating" effects of alcohol, then, are rather apparent than real, for in nearly every case the phenomena may be shown to be really depressions of the inhibitory phase of the balance-control which is so common in the organic functions.

Admitting that there are some unsolved points still in the physiological action of large doses of alcohol, the above statements seem at the present time wholly safe as a rule of advice for physicians to use in their practice, especially since in this grave matter it is undeniably expedient always to be on the safe side. Here one can be at the same time pragmatic and entirely scientific and sincere. It is to practical medical men that the world will most gladly listen in this as in other respects relating to their physical welfare and the true physician will always recognize in his responsibility a privilege.

FERMENTATION DISEASES.

Beriberi, scurvy, cholera nostras, pellagra, and aphthæ tropicæ which are believed by many to be caused, to some extent at least, by some error in alimentation, are grouped by Kohlbrugge (*Centralblatt für Bakteriologie*, etc. I Abt. Orig., Bd. 60 Heft 3 and 4) under the name of fermentation diseases. In the article mentioned he attempts to establish certain analogies between the different members of the group. Working principally with beriberi he found that it resulted from the ingestion of polished rice, and that it could be prevented or even cured by the feeding of rice bran. If rice is sterilized at 120° C. and then exposed to the air it undergoes a fermentation due to the growth of a short, thick bacillus which he has named *Bacillus oryzæ*. Fowl, when fed with sterilized rice, together with a culture of this organism, developed a disease which was apparently identical with beriberi in man. The organism seemed, however, to be harmless when injected into the peritoneal cavity, or into the muscles. This organism is a constant inhabitant of the air, although its virulence is markedly influenced by the season. Kohlbrugge found, also, that it occurs plentifully in the mortar of walls, and offers this in explanation of the existence of "beriberi houses." It develops first in the water-soluble starch in the interior of the grain, and when the rice is cooked in a large quantity of water so as to wash out the starch, or together with bran so that the starch is not dissolved, the bacillus does not grow. Rice so prepared has always failed to produce the disease in fowls.

The same organism was found in the peritoneum and duodenum of guinea pigs suffering with experimental scurvy, and Kohlbrugge thinks it has a causal relation to this disease as well. Whether the fermentative processes caused by this bacillus result in the production of toxic substances or whether they break down some substance necessary to the body is a problem the solution of which will probably be accompanied by a clearing up of the whole question. Scurvy is effectually treated with the acid juices of the citrus fruits and green vegetables. Cholera nostras patients are frequently benefited by the ingestion of hydrochloric acid or the lactic acid bacillus. Aphthæ tropicæ or sprue is usually treated with the acid juice of the pineapple. In the same way Kohlbrugge finds that rice bran under favorable circumstances develops a very marked acidity, and it is to the absence of the acidity so produced that he attributes the causative action of polished rice in beriberi. Certain it is that the development of this bacillus is strongly hindered in the presence of acids, although he admits that these curative foods may act in some other way than simply by acid formation.

In view of the remarkable analogy in certain things which he has been able to demonstrate in these diseases, he seems justified in the formation of the group. Pellagra, he has not touched, but it is to be expected that he will try the effect of his new bacillus upon sterilized corn and in this way may furnish us with valuable information.

QUIET ZONES FOR SCHOOLS.

The movement for quiet zones for hospitals, begun in this city several years ago by Mrs. Isaac L. Rice, the indefatigable founder of the Society for the Suppression of Unnecessary Noises, so commended itself to physicians and all interested in the welfare of the sick that it has spread with rapidity, and the "hospital zones" are now established in a large number of cities thoughout the United States. Encouraged by the success of this undertaking, Mrs. Rice now suggests the establishment of similar quiet zones around school houses in the large cities. In the *Forum* for December, in an article outlining the plan, she urges the importance of "protecting the young from the injurious effect of outside noise, which, by rendering concentration difficult, increases the mental effort required for school tasks, and by preventing free ventilation menaces the physical well being of the child. This is a matter so grave and so far-reaching in its consequences that its utter neglect is little short of incredible." It was while she was talking to the children in the schools on the duty of keeping quiet in the neighborhood of hospitals that the matter was brought forcibly to Mrs. Rice's notice. She was then astonished, she says, to discover the amount of preventable noise which penetrated the classrooms and the foulness of the air within them, this being due to the fact that in most cases the windows were tightly closed. The children seemed dull and apathetic, a fact which, under the circumstances, was not at all surprising, and the teachers complained bitterly of the noise which compelled them to keep the windows closed.

That no attempt has ever before been made to mitigate this evil is evidently due to the fact that it was not brought to public notice, for immediately upon their attention being directed to this question educational and health boards all over the country addressed themselves to the abatement of the evil. Within a few weeks after Mrs. Rice exposed her plan for quiet zones around schools it was enthusiastically endorsed by twenty-five State boards of health and by the school superintendents of seventy cities. The New York Board of Aldermen on November 21 passed an ordinance establishing school zones in this city and their example will doubtless soon be followed by other municipal governments. The task will not be an easy one, for many of the school houses are in parts of the city where the street traffic is heavy and where the necessities of business and manufacture are incompatible with absolute quiet. In many districts, however, relative quiet can be easily enforced and in all some improvement can certainly be obtained.

THE ATTACK ON DR. DOTY.

The report of C. N. Bulger of Oswego, who was appointed last summer by Governor Dix to investigate the affairs of the New York Quarantine, has, after many months, been presented to the Governor. Of course the report is adverse, for the examiner made it very evident by his actions last summer that he considered himself in the light of a prosecutor rather than of an impartial investigator. There are few injunctions of the Decalogue that he does not accuse Dr. Doty of having broken, either himself or through his subordinates. He would have been wise, however, to stop there, for any man is deemed competent to call another a thief and a liar, but when he comes to charges of medical mismanagement Mr. Bulger flounders ludicrously. He is a lawyer from the shores of Lake Ontario and knows as much of medicine and of quarantine methods as such a man might be supposed to know. Furthermore, he comes from a cool climate, and the extreme heat of New York during last summer evidently affected him in such a way as at times to warp his judgment. The report recommends the dismissal of the Health Officer, but we doubt not Governor Dix will hesitate before doing as Mr. Bulger advises. He knows, as evidently the examiner does not, the danger to which this city and the entire country would be exposed were an inexperienced man in charge of quarantine during the coming summer when cholera will be threatening us from both Russia and Italy, from the North Sea ports and from the Mediterranean. He knows also that if cholera becomes epidemic in New York next summer some one will be held responsible for it, and whoever he may be there will be none to envy him.

A REGRETTABLE OCCURRENCE.

In our news columns last week reference was made to an article, apparently inspired, in the *New York Times* of Sunday, November 26, upon the treatment of arteriosclerosis by means of an aphrodisiac drug. The article was entitled, "Can dreaded hardening of arteries now be cured?" and was in the usual Sunday supplement style, illustrated, and adorned with the picture of Dr. Bruno Fellner, Jr., of Franzensbad, Austria, who was announced as the bearer of this message of salvation to the aging and the aged. The article was said to have been read by Dr. Fellner before the Medical Association of the Greater City of New York. It began with a reprint, without credit, of an editorial note in the MEDICAL RECORD, and closed with a description of the operating pavilion for thoracic surgery at the German Hospital in this city, taken from an article by Dr. Willy Meyer in the MEDICAL RECORD of June 17 of this year. The reference to thoracic surgery had no logical connection with the subject of the article, but seemed to have been dragged in solely to give the impression that the New York surgeon endorsed Dr. Fellner's work, and Dr. Meyer has requested us to state that he had never heard of the writer or his work, and that the extract from the paper on thoracic surgery was printed without his permission even being asked.

The above, and more, was already in type when a communication was received from Dr. Fellner, too late for insertion, which shows him to have been more sinned against than sinning. His statement, in brief, is that upon his arrival here, a stranger to the ways of the country (and probably, we may add, with the idea so prevalent in Europe that this is the land of *réclame*), he was advised by a friend to see some of the physicians in New York and also the medical editor of the *New York Times*. His friend explained that it was customary for physicians to announce their discoveries in the Sunday papers, instancing an article relating to the work of the Drs. Mayo, another descriptive of some wonderful operation said to have been recently performed in Phil-

adelphia, etc. Dr. Fellner says he gave the medical editor some German reprints and had but a very brief talk with him, the editor doing the rest. He denies that he said he was to read the paper before the Medical Association of the Greater City of New York, he said and knew nothing of Dr. Willy Meyer's work at the German Hospital, and he had never before had the privilege of reading the editorial note purloined from the MEDICAL RECORD. We are glad to give publicity to this disclaimer, for the article in the *New York Times* had created a very painful impression among the medical profession of the city, and without an explanation Dr. Fellner would have suffered in reputation.

News of the Week.

Death Rate of New York City Increases.—The death rate for the week ending November 25 was 14.43, while for the corresponding week of 1910 it was 13.95 per 1,000 population. The increase was in 14 deaths from typhoid fever, which was nearly three times as many as last year, 200 from pneumonia, 170 from pulmonary tuberculosis, and 187 from heart disease. There were 330 deaths of children under five years of age, an increase of 28 over last year.

Vital Statistics in Kansas.—For the first time in the history of the State vital statistics have been collected for almost a month. The compilation has been made under the new vital statistics law passed by the last Legislature. The total number of deaths recorded was 896. There were more deaths of infants than of any other class. Tuberculosis, which it was supposed was causing more deaths than any other disease was third in the list; diarrhea caused more deaths than tuberculosis.

Railroad Accidents Increase.—The Public Service Commission reports that for the month of October there was a considerable increase in the number of railway accidents but a decrease in the number of deaths and serious injuries as compared with the same months last year. The accidents numbered 5,488 against 5,302 in October, 1910, and 4,447 in October, 1909. There were 19 persons killed and 139 seriously injured, while in 1910 27 were killed and 226 seriously injured.

Steamship Brings Smallpox.—The steamship *Calabria*, which reached quarantine on November 28, had on board a case of smallpox in a two-year-old child. All of the steerage passengers have been held for observation.

Typhoid Epidemic in Prison.—There are at present one hundred cases of typhoid fever in the New Jersey State prison at Trenton and it is feared that the disease will become general among the inmates.

"Typhoid Mary" Sues for Damages.—Mary Mallon, who was designated as a "typhoid carrier" by the Board of Health of New York City several years ago and confined for a time on North Brother Island, is to bring suit against the city for $50,000. When she was released from the Island she agreed that she would not again take a place as cook, and she now alleges that this, together with her notoriety as a germ carrier, makes it impossible for her to gain a livelihood.

Pure Food Policy of the New York Health Department.—Possessing powers that rival those of the Department of Agriculture at Washington, the New York Health Department has entered upon a campaign for the enforcement of pure food laws. It no longer places great reliance on condemnation of food by the inspectors, since by this the offender suffers only the loss of the material condemned. Dr. Lederle is receiving the effective cooperation from the judges of the Court of Special Sessions and feels assured that with the imposition of substantial fines and jail sentences the offenders against the food sections of the Sanitary Code will be found more anxious to obey the law. On November 20 the Commissioner of Health has 101 cases on the calendar of the court on account of different varieties of food exposed for sale that were unfit for human consumption, and this is typical of the Health Department's activities for several months past.

Overcrowding in the Tombs.—At the third annual State Conference of Magistrates to be held in Albany, Dr. George M. Parker, examiner for the New York Prison Association, will present the subjects of overcrowding and insanity in the Tombs. During his inspections of the past three years he has found the Tombs very much overcrowded and suggests as a remedy the building of a psychopathic ward and hospital. During his service he has seen 200 cases of the most violent, maniacal, depressed, and suicidal forms of insanity, but he claims that if the percentage of mental defectives is proportionate to that in Europe there have been during the past three years 1,500 belonging to the defective or insane classes. If this analogy holds good there have been 1,300 insane or defective prisoners in whom the prison authorities have failed to recognize the condition. For many reasons these should be segregated from the other prisoners.

May Ostracize Lodge Doctors.—The Omaha Douglas County Medical Society has appointed a committee to consider and recommend a proper penalty to be imposed on members who do not respect the resolutions of the Society forbidding lodge practice. This action has been brought about by the situation in Council Bluffs where fraternal lodges sprang up in such numbers that 12,000 people, more than one-third of the population of the city, were being given free medical treatment by the physicians of their orders. It is reported that physicians were getting as low as twenty-five cents per call.

Physicians' Names Barred from Newspaper Stories.—The physicians of Moberly, Mo., have formed a union pledging themselves to stand by a new schedule of fees and to pay a fine of not less than $25 nor more than $100 for each infraction of the scale. They have also agreed to forbid the use of any physician's name in connection with the news story of a case. The penalty for an infraction of this agreement is that the paper will be boycotted by the physicians.

Licenses to Practise Medicine Few in Idaho.—The State Board of Medical Examiners announces that of the twenty-two applicants for licenses to practise medicine in Idaho, only sixteen were successful, and a number of these passed by a very small margin.

Court Upholds Health Board.—The Appellate Division of the Supreme Court handed down a decision on December 1 upholding the appeal of the Department of Health of New York City from a lower court order granting Dr. William H. Allen of the Bureau of Municipal Research permission to examine its records. The Appellate Division holds that public policy is opposed to the policy of giving taxpayers the right to inspect the private records

of a department of the character of the Health Department. It is also denied that the Bureau of Municipal Research has any peculiar rights to delve into the records of the department. The Legislature appreciated the evil that might arise from indiscriminate publicity of the records of the Department of Health and left it to the Department to determine what safeguards should protect the privacy of its records.

Christian Scientists Arraigned.—A Mrs. Mosbach of New York City, whose child died recently from diphtheria while under Christian Science treatment, has been arrested under a warrant issued by Coroner Shongut, charging her with homicide. The County Medical Society has also begun an investigation of the case and was represented at the inquest, and will endeavor to make out a case against Mr. and Mrs. Ephraim Roberts, the Christian Scientist practitioners, who treated the child.

Dr. Robert W. Brace, assistant demonstrator of anatomy in Jefferson Medical College, has been appointed Colonial Surgeon for the Bahama Islands.

Dr. Edward Livingston Hunt has been appointed Associate Consulting Neurologist to St. Luke's Hospital.

Dr. De Keating Hart of Paris lectured at the New York Skin and Cancer Hospital on the evening of December 4 on "The Fulguration Treatment of Cancer." On the following days of the week he gave practical demonstrations on patients using the new fulguration apparatus of the hospital.

Dr. George Gray Ward, Jr., has moved to 71 W. 50th street.

A Doctor in the Pulpit.—Dr. Richard C. Cabot of the Harvard Medical School and Massachusetts General Hospital of Boston spoke on "The Modern Conception of Medical Service with a Retrospect," Sunday, December 3, at the Mount Morris Baptist Church. He was introduced to the congregation by Dr. Abraham Jacobi. Others on the platform were Dr. William M. Polk and Dr. Wendell C. Phillips.

The Presbyterian Hospital celebrated the forty-third anniversary of its founding on the afternoon of December 2. Dr. William H. Welch of Baltimore made the address on this occasion, taking as his theme "The Advantage to a Charitable Hospital of Affiliation with a University Medical School. His address was largely commendatory of the step the Presbyterian Hospital had taken in affiliating itself with the College of Physicians and Surgeons of Columbia University. He thought that by taking this step they had done a great service to medical education. It was announced that the offer of Edward S. Harkness to erect a surgical pavilion of 150 beds and a laboratory fully equipped for advanced research work, and also the offer of an endowment fund of $1,300,000 to be known as the Harkness Fund had been accepted.

Tuberculosis Hospital for Westchester.—The Board of Supervisors of Westchester County has decided to build a hospital which will accommodate about 200 tuberculosis patients and will cost about $200,000.

The New Solarium of the Methodist Hospital of Philadelphia, erected at a cost of $11,000 by Mr. Frank A. Freeman, was dedicated on November 25. It is said to be one of the finest and best equipped structures of its kind in the United States.

Charitable Bequests.—By the will of the late Leile H. Sharpless of Philadelphia $5,000 is bequeathed to the Home of the Merciful Saviour for Crippled Children for the establishment of a free bed in memory of Caroline Norris Horwitz. The Heaton Hospital of Montpelier, Vt., has received a bequest of $5,000 under the will of Mary Walton Dewey of Cambridge, Mass. Thrall Hospital at Middletown, N. Y., received a Thanksgiving gift of $5,000 from the Ontario and Western Railroad, and also a residuary bequest of $1,000.

The Surgeon-General of the Marine-Hospital Service.—The names of two candidates are mentioned as successor of Dr. Wyman as Surgeon-General of the Public Health and Marine-Hospital Service. These are Dr. Rupert Blue, at present in Hawaii, who had charge of the plague campaign in San Francisco, and Dr. J. H. White, at present in New Orleans. It is stated in the papers that the appointment has been tendered to Dr. Blue.

A New Hospital in The Bronx.—The State Board of Charities has approved the application of the Bronx Hospital Organization and has granted a charter authorizing the establishment of the hospital. The medical staff of the hospital is constituted as follows: Internal Medicine, Drs. A. Jacobi, Samuel W. Lambert, M. Aronson, Alex. Goldman; General Surgery, Drs. Willy Meyer, Arpad Gerster, A. A. Berg, Martin Rehling, J. C. Arpad Gerster, J. M. Lipschutz, A. L. Goldwater; Gynecology, Drs. Joseph Brettauer, Francis Foerster, R. T. Frank, Ulysses S. Kahn; Pediatrics, Drs. Henry Heiman, Henry Schumer, S. Feldstein; Nervous Diseases, Dr. George W. Jacoby; Genito-urinary Diseases and Dermatology, Dr. William J. Robinson; Ophthalmology, Drs. Emil Gruening Otto Schirmer, M. Aronson; Ear, Nose and Throat, Drs. W. Freudenthal, I. M. Heller, Alfred Braun.

The United States Civil Service Commission announces an examination to be held on December 6 to secure eligibles from which to fill a vacancy in the position of aid in the Division of Physical Anthropology, U. S. National Museum.

The Bronx Medical Society will meet on the evening of December 13, when Dr. Charles E. Nammack of Bellevue and St. Vincent Hospitals will read a paper on "The Treatment of Acute Lobar Pneumonia."

The Sixth Harvey Society Lecture will be delivered at the New York Academy of Medicine on December 16 by Prof. Walter B. Cannon of Harvard University. His subject will be "A Consideration of the Nature of Hunger."

The "New York Medical Times" has been purchased and will hereafter be published by Mr. Romaine Pierson, publisher of the *Practical Druggist.*

National Association for the Study and Education of Exceptional Children.—The Second Annual Conference on the Problem of the Exceptional Child was held December 1 and 2 under the presidency of Dr. A. Emil Schmitt of New York City. There was a very good attendance and nineteen papers were read. The following are among the activities of this association: The gathering of statistics and other information as to the number and various types of exceptional children, and provisions for their care, in the United States, and eventually abroad; a reference library; an information bureau; a publicity bureau; a pedagogical library; a sanatorium school; an odservation clinic for the care and study of borderland cases, where a positive prognosis of eventual restoration to a fair degree of normality, or of permanent defectiveness must be based on extended observa-

tion; an adolescent department for ineffective persons between the ages of 16 and 25; courses for the training of teachers.

Medical Society of the County of New York.—At the meeting held November 27 the following officers were elected: *President,* Dr. Charles Gilmore Kerley; *First Vice-President,* Dr. Brooks H. Wells; *Second Vice-President,* Dr. T. Passmore Berens; *Secretary,* Dr. John Van Doren Young; *Assistant Secretary,* Dr. J. Milton Mabbott; *Treasurer,* Dr. Charles H. Richardson; *Censors* (to serve three years), Drs. Edward S. Peck, H. Seymour Houghton, and Frederick E. Sondern.

German Medical Society of the City of New York.—At the meeting of this society held December 4, the following officers were elected: *President,* Dr. Carl Pfister; *Vice-President,* Dr. A. Ripperger; *Recording Secretary,* Dr. H. O. Klein; *Corresponding Secretary,* Dr. A. Herzfeld; *Treasurer,* Dr. S. Breitenfeld.

The International Congress of Hygiene and Demography will hold its fifteenth annual meeting in Washington, D. C., September 23-28, 1912. Although this congress has been in existence for many years this will be the first time that it has met on American soil.

Society of Sanitary and Moral Prophylaxis.—A meeting of this Society will be held at the New York Academy of Medicine on December 14. The general subject for discussion will be "Practical Eugenics," opened by a paper, based on observation of several hundred cases of sterilization of criminals, by Dr. F. N. Hurty, Secretary of the Indiana State Board of Health.

The Missouri Association for the Relief and Control of Tuberculosis, which met in Jefferson City on November 13, elected the following officers: *President,* Dr. George Dock of St. Louis; *Treasurer,* Mr. Saunders Norvell of St. Louis; *Secretary,* Dr. Walter McN. Miller of Columbia. It was agreed that the Association would undertake the organization of county societies and should endeavor to enlist the cooperation of the press, medical men, the clergy, and organizations and people interested in public welfare.

The Fourth District Medical Association of South Carolina met in Union on November 20, when the following officers were elected: *President,* Dr. Theodore Maddox of Union; *Vice-President,* Dr. Fred H. Potts of Spartanburg; *Secretary,* Dr. W. E. Carpenter of Greenville.

The Lebanon Hospital.—The dedication of the new dispensary building of Lebanon Hospital and the inauguration of a department of social service will take place on Sunday, December 17, at 3 o'clock. Addresses will be delivered by Dr. Abraham Jacobi and the Rev. Dr. Stephen Wise.

The New Utrecht Medical Society is the name of a new organization established in the Borough Park section of Brooklyn. The following officers have been elected: *President,* Dr. J. Bertram Dowd; *Vice-President,* Dr. Henry M. Kalvin; *Secretary,* Dr. Murray B. Gordon; *Treasurer,* Dr. Max S. Ittelson; *Trustees,* Drs. John J. Masterson, Abraham J. Schwartz, and Thomas E. Waldil.

Obituary Notes.—Dr. Henry Phelps Perkins died suddenly at his home in West Newton, Mass., on November 26. He was born in Lowell in 1860, and was graduated from the Harvard Medical School in 1881. He was senior surgeon at the Newton Hospital.

Dr. Oscar A. Bemis of Whitman, Mass., dropped dead on the street, November 21. He was 65 years of age and a graduate of the Homeopathic Hospital of Philadelphia.

Dr. James B. Kelly died in Portland, Ore., on November 2 at the age of 51.

Dr. Augustus Beekman Smith died at his home in New Haven, Conn., November 12. He was a well-known dentist and brought to perfection the first set of teeth ever set in vulcanized rubber. He was 85 years old.

Dr. Michael Nienhardt of Lafayette, Ind., a graduate of the Indiana Medical College in 1897, died on November 10 at the age of 70.

Dr. J. E. Perry of Welborn, Fla., died in a sanatorium in Atlanta, Ga., on November 4 at the age of 64.

Dr. Walter Washington of Bowling Green, Va., died on November 7 after a long illness at the age of 87.

Dr. Ethel M. Kirk of Pittsburgh, Pa., was found dead in her apartment on November 16. She was 30 years old.

Dr. Asa D. Smith, a graduate of the Boston University Medical School in 1878, and a Civil War veteran, died suddenly at his home in Boston on November 25 at the age of 76 years.

Dr. Oscar L. Lyndon of Athens, Ga., dropped dead in Atlanta on November 20, immediately after witnessing a football game. He was graduated from the University of Georgia in 1899.

Dr. Frederick C. Graves died of pneumonia at his home in New Bedford, Mass., on November 22. He was born in 1874 and was graduated from the Homeopathic Medical College and Flower Hospital, New York, in 1899. He was a member of the local health board and a medical inspector for the schools.

Dr. Orville E. Evans died at his home in Gowrie, Iowa, on November 22. He was born in 1846, was a Civil War veteran, and a graduate of the College of Physicians and Surgeons, Keokuk, Iowa, in 1878.

Dr. Frederick A. Leahey, a graduate of Harvard Medical School in 1900, died at his home in Lowell, Mass., on November 24 at the age of 34 years.

Dr. Charles D. King died at his home in Brockton, Mass., on November 24 at the age of 64 years. He formerly practised medicine in Minneapolis and St. Paul, Minn., and moved to Brockton about twenty years ago.

Dr. Henry C. Bullock, one of the oldest practising dentists in the State of Connecticut, died at his home in Hartford on November 23. He was born in 1846 and was prominent in the affairs of the First Regiment, C. N. G., being a lieutenant on the staff of Colonel Philip Hedson at the time of the Centennial Exposition in Philadelphia in 1876.

Dr. Oliver Fairfield Wadsworth died at his residence on Beacon street, Boston, after an illness of a year, on November 29 at the age of 73 years. He was graduated from Harvard in 1860, and three years later took his A. M. degree. In 1865 he was graduated from the Harvard Medical School, where he was an instructor in ophthalmoscopy from 1881 to 1891; he was then appointed professor of ophthalmoscopy, which position he held until he received the appointment as Williams professor. He was ophthalmic surgeon at the Boston City Hospital and consulting surgeon at the Massachusetts Eye and Ear Hospital and also at the Massachusetts General Hospital for a number of years.

Correspondence.

THE REMSEN BOARD AND DR. WILEY.

To the Editor of the Medical Record:

Sir:—The public has been so thoroughly hoodwinked regarding the scientific work of Dr. Wiley that it seems necessary that some one who understands the truth of the matter should speak.

A few years ago Dr. Wiley established a poison squad. A number of young men were given benzoate of soda with their food, and it was found that they became ill. The maximal amount received by any individual in this series of experiments was 41 grams (about 1½ ounces) distributed in small doses through a period of twenty days. As the result of these experiments, Dr. Wiley has never ceased to insist that benzoate of soda is a poison. Reiteration of this statement has made people believe that the statement itself is true.

The work of the scientist is usually accomplished in the quiet of his laboratory without flourish of trumpets, without newspaper notoriety. An earnest endeavor to separate scientific truth from the influence of psychic turmoil must be the aim of the scientific man. Dr. Wiley's experiments on the contrary were trumpeted abroad. The young men who were the victims must have been more than human not to have been influenced mentally by this course of their chief. They had a fever, many of them, and Dr. Wiley was so alarmed that he discontinued the experiments. Authorities have, however, suggested that the febrile symptoms noticed in this group of men were in reality those of an epidemic of the grippe. It appeared to many that the experiments were not entirely satisfactory, especially after it was learned through an investigation held in Washington that the majority of the individuals employed in the experiment had been used as subjects in previous experiments in which they had been made ill as a result of their ingestion of various deleterious substances. Some of them testified that they fully expected to be made ill by benzoate of soda. Furthermore, the benzoate was administered in capsules and not in diffused state as it would have been had it been taken in preserved food.

It did not seem to be right that the judgment of a single man should be accepted as final scientific truth, especially when the course of experimental procedure employed by that individual was open to criticism. In recognition of this fact the Remsen board was appointed by the Government. It has been freely stated that it would be very much cheaper for the government to abolish the Remsen board and to place the judgment with regard to all such matters in the hands of Dr. Wiley solely. The proposition appears to be that doctrines taught by one man should be accepted as the truth by 90,000,000 people. If the popular state of mind be such, that personal idolatry of Dr. Wiley is to crown him with the added attribute of infallibility, one must go back to the middle ages to find in the worship of the authority of Galen a similar parallel. It will be remembered that Galen, who was born at Troy and who died at Rome in the year 200 A.D., taught medical doctrines, disbelief in which was held to be heresy by the medieval church.

Dr. Wiley and the newspapers unite together in proclaiming that the work of Dr. Wiley is hampered by the Remsen board. Who are the men who are hampering Dr. Wiley? President Remsen of the Johns Hopkins University is the chairman of the Remsen board. Remsen received his education in Germany. It was he who discovered saccharin which was placed upon the market by a German firm, it having been patented without his permission, the profits going to the German patentee. In my student days in Germany a translation of Remsen's book on organic chemistry was largely sold to German students. He is a man of undoubted integrity and high culture.

Professor Chittenden, Dean of the Sheffield Scientific School, is one of the few Americans who have developed a school of trained pupils. One speaks of the school of Liebig, meaning the men whom Liebig trained. One speaks of the men of the Chittenden School, meaning the physiological chemists who, throughout the country, hold important chairs of physiological chemistry and of physiology, as members of the Chittenden school. He is a man of great power and great capacity.

The late Dr. Christian A. Herter was a man of high ideals, a man who endowed lectureships at the Johns Hopkins and at the University of Bellevue Hospital Medical School, a man who was acquainted with the great scientists of the world. Dr. Herter's private laboratory was carried on at his own expense. One of his chief assistants was Dr. Dakin, an Englishman whom the English considered the best chemist they had in their country.

Professor Long is a man of experience and long service, who has done much work for the United States government in the examination of food and drugs for the Indian Service. Associated with him in the work of the Remsen board was Dr. Stanley R. Benedict, one of my colleagues at Cornell.

One of my own assistants, Dr. A. I. Ringer, was in the laboratory of Dr. Herter, and for his careful accuracy I can vouch. These men are men whom I know personally, whose integrity I am sure of, whose work I can rely upon, and these men, after many months of hard labor, came to the conclusion that Dr. Wiley's results were absolutely wrong. Investigations were carried on in three laboratories. In Dr. Herter's in New York City, in Dr. Chittenden's in New Haven, and in Professor Long's in Chicago. It was thought best that all of the experiments should be as independent as possible, so that the truth should be arrived at without bias. On account of Dr. Wiley's belief that benzoate of soda was a poison, it was at first given only in small doses. Dr. Herter, however, learned that Lewinsky, a pupil in the clinic of the great Minkowski, had given nearly two ounces (50 grams) of benzoate of soda to a man in one dose without injuring him. Dr. Herter increased the dose which he gave. Dr. Ringer, for example, took a fifth of an ounce of benzoate of soda (6 grams) without the slightest change in his condition, which could be interpreted as being detrimental. He, with the other men employed, took, through a period of three or four months, dietaries containing from 0.3 to 6 grams of benzoate of soda daily.

Here then were three individual laboratories working under the care of great and experienced men, all arriving at the same result, and all of them deciding that Dr. Wiley's experiments were wrong. These men were the ones to whom the country particularly could look to decide this question, and Dr. Wiley has stated that he has a very slight opinion of their scientific worth. It seems to those who are really in a position to know the truth about the matter that there has been no controversy in this country where the general public has been more com-

pletely and absolutely misled as in this question of the relative reliability of Dr. Wiley's statement on the one side and the statement of the Remsen board on the other. Every newspaper from one end of the land to the other is, apparently, willing to place complete control of the regulation of the preservation of food in the hands of a man whose experimental work has been shown to be erroneous.

Certain experiments made by Dr. Lucas have been widely quoted. Dr. Lucas was one of the subjects in Dr. Herter's laboratory. During his stay in this laboratory information was given to the newspapers which was traced to a conversation of Dr. Lucas. In consequence of this, Dr. Lucas received a severe reprimand from Dr. Herter. Passing from Dr. Herter's laboratory, he went to another, from which he published an article in direct antagonism to the findings of the Remsen board. Dr. Herter, criticising this work of Lucas, stated "Dr. D. R. Lucas has published certain statements in regard to the action of benzoate of soda which are so much at variance with the facts as to call for criticism and correction. I deem it my duty to make at least some comment, despite the fact that this work is highly distasteful to me." Dr. Herter, after reviewing the work of Dr. Lucas, stated that "if it were worth while to cite further examples of untrue statements with which this paper abounds it would be an easy undertaking." The newspaper press which quotes the article of Lucas does not measure the relative personal equation which distinguishes Dr. Lucas from the scientific men whose pupil he was in the Herter laboratory. These experiments of Lucas are the only ones ever reported as confirming Dr. Wiley.

The quantity of benzoate of soda which the law permitted to be used as a preservative in three-quarters of a pound of beef was 0.3 of a gram. The subjects experimented on by the Remsen board received twenty times this quantity or one-fifth of an ounce without affecting their health. As above stated, nearly two ounces have been given to a man without injuring him. However, there must be a limit to the dose which can be given. In the laboratory of the writer Dr. Ringer has found that more than an ounce of benzoate of soda may be given to a goat weighing eighty pounds without any disturbing symptoms other than a loss of appetite. Two ounces given in one dose to this same goat killed the animal. This, however, does not conflict with the statement that in small doses benzoate of soda is absolutely innocuous.

As regards the normal action of benzoate of soda, the following facts may be of interest. In the bodies of all animals there is a constant production of a substance called glycocoll. This substance is not a poison, but a normal product of the living tissues. When natural foods containing substances which are convertible into benzoic acid are taken by an animal the benzoic acid unites with glycocoll to form hippuric acid. Hippuric acid is not a poisonous substance.* It is eliminated by the kidneys and is found in the urine. Grass and hay contain substances which form benzoic acid in large quantities, and so there is a large formation of hippuric acid in horses, cattle, goats, rabbits and all herbivorous animals. The same process takes place in man. If huckleberries or cranberries or other related fruits be eaten benzoic acid arises from them in such quantity that the amount of hippuric acid formed may be very considerable. In the same way, when benzoate of soda is given to man with his food it forms benzoic acid, which unites with glycocoll to form hippuric acid, and this passes out in the urine. This capacity does not have to be acquired. It is always present, even in infants. There is nothing mysterious about this. It is based on well-known physiological functions. The organism is adapted to render harmless benzoic acid administered to it in small quantities.

The argument here presented is in no way intended to dispute the decision of the Prussian Deputation for Medical Affairs that to allow the use of benzoate of soda in the preservation of food would enable the manufacturer to practice methods less cleanly than he should.

And finally let the reader consider for a moment the following illuminating testimony given by Mr. McCabe (Committee on Expenditures in the Department of Agriculture, August 7, 1911, p. 511.) "There was a correspondent here in Washington almost from the time that the board was created who sent out any number of copies of articles reproduced by a typewritten process abusing the Secretary, abusing the referee board, impugning the motives of the Secretary for creating the board, attacking the personnel of the referee board; and those articles have continued to be sent out up to within certainly a very few days."

This letter has been written for the public statement of the truth regarding the relations of benzoate of soda to health. It has seemed a public duty which ought not to be evaded.

GRAHAM LUSK.

DEPARTMENT OF PHYSIOLOGY, CORNELL UNIVERSITY MEDICAL COLLEGE, NEW YORK.

*Wiley, with a reckless disregard for well-established fact, told Congress (the Committee on Interstate and Foreign Commerce, February 26, 1906, p. 245), the following: "If the kidneys should cease to act for twenty-four hours there is not a man on this committee who would not be at death's door from hippuric acid and the urea which would be in the blood. Hippuric acid is perhaps far more poisonous than urea. It is a deadly poison."

RHEUMATISM AND APPENDICITIS.

TO THE EDITOR OF THE MEDICAL RECORD:

SIR:—In view of your editorial comment in the issue of November 18, the following quotation from Sir Frederick Treves's address in 1907 at the University College of Liverpool, seems appropriate at the present time, *apropos* of appendicitis and its treatment. He said: "A man may possess all the learning that a well-equipped library may contain and all the erudition attentive observation in the wards may bestow, and yet know too little of man himself and the fixed natural laws which govern his existence. . . . Disease is the result of the violation of some of Nature's laws, and it is the duty of the physician to find out the law which has been violated, and as a remedy, impress upon the patient the necessity of mending his conduct, so as to more fully comply with the laws of Nature."

In appendicitis the frequent underlying cause is rheumatism and the evidence pathologically, from even the late remarkable experimental proof of it by Poynton and Paine, is the accompanying local peritonitis which is often present.

The localized peritoneal inflammation not infrequently starts, as I believe, the inflammation in the appendix and not the appendix the inflammation in the peritoneum.

In either case, get rid if possible, of the primary cause by diet, habits, régime, and the use of salicin

or salicylate of soda, and the number of cases of appendicitis will greatly diminish.

Institute rational, effective treatment at the beginning of an attack and fewer operations will be required.

As to fulminating cases, operate immediately, or preferably, as I believe, wait for one of two things: (1) Perforation; (2) local abscess. In either of these circumstances operation is surely indicated.

It must be remembered, however, that acute general peritonitis does not invariably mean perforation, and as this is true, when no perforation exists, even immediate operation does not increase the chances of the patients' recovery as compared with those from wise medical treatment.

Further, there are many cases of appendicitis confounded with, or preceded and caused by, colitis. If we get rid of the colitis the appendicitis, when it exists, will disappear also.

BEVERLEY ROBINSON, M.D.

NEW YORK.

OUR LONDON LETTER.

(From Our Regular Correspondent.)

MEETING AT ROYAL COLLEGE OF SURGEONS; OBJECTIONS TO INSURANCE BILL—PARLIAMENTARY CRITICISM ALSO—PHTHISIS COMPULSORILY NOTIFIABLE—NAVAL MEDICAL REFORMS—WASSERMANN REACTION (HUNTERIAN LECTURE, ETC.) ANESTHESIA—BALNEOLOGY—OBITUARY.

LONDON, November 17, 1911.

YESTERDAY the annual meeting of the Fellows and members of the Royal College of Surgeons was held. Mr. Godlee presided, and in opening referred sympathetically to the resignation of Sir H. T. Butlin on account of ill health. A message of sympathy was sent from the assembly. Mr. Nelson Handy moved a resolution thanking the Council for writing to the Chancellor of the Exchequer on the insurance bill, regretting the unsatisfactory reply and trusting no Fellow or Member will assist the scheme until the points in dispute are arranged. Mr. Handy pointed out that the Chancellor spoke of the Council's proposals being in accordance with his own, whereas when parliament placed the medical benefits in the control of the Health Committees the Chancellor promised the Friendly Societies to reverse it on report. Moreover, he has so far refused to reduce the income limit which the Council urged and the profession is determined upon. Mr. Maude seconded and said the Chancellor's amendments gave back to the clubs 50 per cent. representatives and only 2 per cent. to the profession.

Mr. Collingwood insisted on payment by fee, however small it might be, rather than any form of contract practice. Another member said the Chancellor is not to be trusted, and on a member expressing dissent, added that by his action about health committees he had annulled his promises to the profession. Another member said that without the help of the profession the Chancellor's scheme must fail, and they could refuse any assistance if it meant continuing the old slavery to the clubs. The resolution was carried, with two dissentients.

While the Chancellor's conduct was being thus condemned in a medical meeting, he was defending himself as well as he could in the House of Commons against charges of misrepresentation about his bill and the opposition. He does not often lose his temper in the house, but this time he seemed to do so. The chairman of the committee had to request him to confine himself to the question. There were several new clauses put forward by the Chancellor, one of which, he admitted, affected numerous and important bodies of employees. There were some remarks upon it and then, with 18 others, it received the happy dispatch of the guillotine. It seems absurd to call these proceedings discussion.

Yesterday the local government board issued to all health authorities a general order extending compulsory notification of all cases of pulmonary tuberculosis. The disease was previously notifiable in hospitals, infirmaries and similar institutions, but henceforth it becomes the duty of every medical practitioner to notify every case occurring in the course either of his public or of his private practice.

The naval medical service appreciates the reforms recently carried out by the Director-General, Sir James Porter, on the recommendation of the Burnford committee. One of the most satisfactory is the recognition of professional ability as a claim for promotion in place of too much consideration of seniority or war service. To give every opportunity, the new school at the Royal Naval College at Greenwich with its laboratories will, it is hoped, be in working order by the end of the year. The Seamen's Hospital (Dreadnought) close by will furnish a field for clinical study. The School of Tropical Medicine, also near, will be of great use. As soon as he enters the service the naval surgeon will take a two months' course at Greenwich and then pass to Haslar. After four months there he will go to a ship. In from four to six he will obtain another six months' course and must then pass the examination for staff surgeon. When he has attained fourteen years' seniority he can take a final three months' course. It is obvious that these regulations afford full opportunity for keeping in touch with the advances of medical science and practice. "Conspicuous professional merit" is at length recognized as of the first importance and as the proper qualification for promotion. Coincidentally with these reforms, the pay of the naval medical service is to be increased. The medical officer of the senior flagship of a fleet is the principal medical officer of that fleet and will have direct access to the commander-in-chief, which will give satisfaction well understood in the service.

I should add here that great improvements have been effected in the equipment of naval hospitals. This is especially noticeable in their operating theaters, which, I am assured, are in no way inferior to those of our great civil hospitals. The open-air treatment is being tried in the grounds of Haslar Hospital. Electric, x-ray, and other methods are mostly under the care of specialists on the staffs of these hospitals and, of course, trained anesthetists are attached to them. It is well to find that the service is no longer to be neglected by the admiralty or ignored by politicians.

The Wassermann reaction has been so frequent a topic of conversation of late that it may well occupy a little of your space. A very important pronouncement was made by Major French, R.A.M.C., in his recent Hunterian lectures at the Royal College of Surgeons, when he took for subject recent developments in the "recognition, treatment, and prophylaxis of syphilis." Confining my notice to-day to the Wassermann test, he dealt with it from the clinical side, as Professor Emery had considered its pathological aspects in last year's Hunterian lectures. Major French said laboratory methods and

clinical facts as to the test do not always correspond as he found at Malta. The controls, with few exceptions, were negative in soldiers giving no history of infection. In the primary stage the results were disappointing, as others had found. In the secondary stage, in patients on a final course of mercury or earlier, the results were positive in 40 out of 43 cases. The reaction was positive in 14 out of 18 cases on their second, third, or fourth mercurial course by intramuscular injections of insoluble grey oil. In one recent case the man was a heavy drinker. In 36 other men who had had two years' treatment by these injections the reaction was positive in 25. In one man who had mercurial stomatitis it was negative. In another negative case gummatous ulceration was present. These results were obtained by Fleming's modification and as regards secondary cases compare favorably with Wassermann's original method. As regards early cases, the results were so difficult of interpretation that the lecturer preferred to relate cases in detail. A year ago he wrote that in the primary period the test had been uncertain in his experience and mentioned then 10 or 12 cases in which a positive reaction was reported to him, but no syphilis supervened, though no mercury was given. If it be suggested that the testing was defective he would add that the pathologist obtained 98 per cent. of positive results in secondary cases—*i.e.* after the rash had appeared. The lecturer quoted the statements of a number of authorities in support of this, and asked whether the assertion of a bacteriologist who said there would be no appeal from a positive finding could be accepted, even with certain limits said to be understood.

In addition to the lecturer's cases of positive reaction in non-infecting, soft sores he cited observations of several observers who reported this reaction in other diseases as yaws (fairly constant), leprosy (very high percentage), malaria (35 per cent.), lupus, enteric fever, and other diseases, in some persons under narcosis and even in dead bodies. In his conclusion, having spoken also of the spirochetes and the clinical evidence, Major French said it "must be admitted that in many instances we are as dependent to-day on a correct clinical interpretation of what we see as in the past, when John Hunter wrote."

At the Liverpool Medical Institution Wassermann has also been under discussion, and one or two of the points brought forward may be quoted. The paper was by Dr. F. P. Wilson, who spoke of the unstable nature of the materials used in the test which necessitated frequent standardization. All apparatus hitherto tried in the consulting room, he declared useless, and a well equipped laboratory was essential. Salvarsan affected the test more rapidly than mercury. The test was not absolute, but rather an adjuvant to the clinical examination. When no symptoms remained after thorough treatment, except a persisting reaction, it could not be asserted that the patient was not cured. But the evidence pointed to such a conclusion. Dr. MacKenna thought the original test better than any modification. He had found the reaction in the third week. It was frequent in the second stage and more so in the third. In a congenital case, with no symptoms until the twenty-fifth year, he had found a strong positive reaction. When two injections of salvarsan were given, separated by a course of mercury, the reaction usually became negative in three or four weeks.

In the section of anesthetics (R.S.M.) on the third inst. three deaths were reported, as well as some cases involving anxiety. Of the latter was one of acute bronchitis, with perhaps pleurisy, in a man of 34, who had 15 ounces of ether by the open method during a long operation. No drug was injected previously. Dr. Silk, who reported the case, thought it was probably one of pulmonary collapse and supported the view that the open method might cause troubles identical with those met with in the closed method. Another case was of persistent vomiting during anesthesia for extraction of teeth. The patient was a girl and had had breakfast. Gas and oxygen were given and afterwards gas alone. Next day she had no breakfast and gas alone was tried and then two doses of ethyl chloride. On the third day ethyl chloride alone was given and the last of the teeth extracted. On every occasion and with every drug vomiting was produced. In the discussion there were suggestions as to preventives, previous gargling with dilute carbolized lotion, or a small dose of cocaine, or increase of pressure in the bag.

Mr. Bellamy Gardner then read a paper insisting on the absolute necessity of maintaining a free oral airway by mouth-prop and tongue clip as a routine in every administration. Nasal breathing, he said, was quite inefficient, and to impress students he suggested the words "asphyxial death space" might be used in teaching.

The opening meeting of the balneological and climatological section was very encouraging to those interested in that department. The president, Dr. Thompson of Buxton gave an address containing reflections and suggestions as to spa treatment and the duty of health resorts to promote the study of their advantages and provide for the necessary accessories. The investigations of Professor His open a new field and the equipment for treatment by radium emanations should be provided in all spas. The president, after his address, invited Dr. Monod of Vichy, who has been sent by the French government to study and report on British health resorts, to explain his mission. Accordingly, Dr. Monod said Dr. Neville Wood's paper last session had evoked much interest abroad and was, he thought, partly responsible for his government's action. He said that the equipment of the spas he had so far visited had impressed him by their completeness for treatment. He considered that many of his countrymen, for whom thorough change of surroundings would be beneficial, might find in England resources not available at home. He closed with a suggestion that spa treatment might well be placed on an international basis. I should think after his testimony those who have rather slighted British spas will give them a higher place in their therapeutic views.

Dr. Samuel McBean, professor of materia medica and therapeutics died on the 6th of November, aged 72. He qualified in 1862 and the same year entered the navy as assistant surgeon. In 1863 he had charge of the naval hospital Yokohama. In 1864 he was at the bombardment of Simonosaki. In 1867 he was in the Niger expedition, and on his return was appointed surgeon to the Chatham Hospital. He retired from the service a year or two later and soon was appointed to the Chair of Botany, afterwards to therapeutics in the Durham University. He wrote the "Origin and Development of Medicine," and contributed to the journals and societies.

The Medico-Psychological Asosciation loses one of its prominent members in the death of Dr. Mur-

ray Lindsay, who was president in 1893. He had been superintendent of the asylums at Derby and Hanwell and held other appointments.

Dr. Kraemar of St. Leonards-on-Sea died on the 15th inst., aged 57. He was M.A. (Edin.), 1878, and subsequently filled the medical curriculum and took M.D. in 1897.

Open-Air Rooms and Hospital Schools. G. S. C. Badger and J. B. Hawes, 2d.
The Copenhagen Institution for Cripples. Its History, Work, and Results. D. C. McMurtrie.

Economic Study of Tuberculosis.—E. A. Locke and C. Floyd note that the total losses in wages, together with the cost of care in public institutions, of 500 patients treated in the Boston Consumptives' Hospital was $500,023. The total potential loss in a group of 244 fatal cases was $1,366,400.

Vaccine Emulsion Treatment of Cancer.—E. H. Risley has subjected to a practical test in twenty cases the method employed by Gilman and Coca of the Philippine General Hospital in the treatment of cancer with a vaccine consisting of an emulsion of the living tumor cells of the patient, removed at operation. The conclusions arrived at are that emulsions or extracts of cancer injected into the inoperable or recently operated patient with recurrent cancer have no effect in retarding the growth or preventing recurrence, but in a great proportion of cases produce an increased activity on the part of the cancer cells, so that tumors grow with greater rapidity, and that the danger of sepsis is marked, such sepsis being in no wise beneficial to the patient.

Metabolism in Diabetes Insipidus.—H. W. Goodall states that all recent investigations of the metabolism in cases of diabetes insipidus conclude that the disease is a functional disorder. The much-discussed question as to whether the polyuria or the polydipsia is the primary symptom is as yet undecided. There is also a difference of opinion as to whether the intake of large amounts of water increases the catabolism of body protein. The author investigated this subject in a female patient aged twenty-eight years, who had suffered from polyuria and polydipsia since she was twelve years of age. He reached the following conclusions: polydipsia was the probable primary cause of the neurosis in this particular case, since with the restriction of liquid intake the kidney excreted a more concentrated urine. The increased catabolism of body protein is the result of undernourishment rather than the ingestion of large quantities of water.

Open-Air Rooms and Hospital Schools.—G. S. C. Badger and J. B. Hawes, 2d, call attention to the fact that it is not fresh-air rooms or hospital schools alone which are to solve the problem of caring for anemic and tuberculous children. These are but two factors in the far wider subject of school hygiene. It is by strengthening, broadening, and combining all forces that the condition of the child is to be improved. Children must be properly taught the principles of hygiene and right living; fresh air must be provided for all school children; trained school physicians must be properly paid for the work they do; school nurses must everywhere be made a part of the system as the most important means of making the school physicians' work effective; there must be fresh-air rooms for ailing children; proper hospital facilities for acutely sick children, and tuberculosis camps or wards for consumptive children. Above all, the public must be educated to see the reason for all this, and to insist upon it.

The Copenhagen Institution for Cripples.—D. C. McMurtrie states that this institution, which was founded in 1872 by Pastor Hans Knudsen, furnishes surgical care and appliances and educates the children with a view to their becoming self-supporting.

The Principles of the Reduction of Infant Mortality. S. J. Baker.
Disease of the Verumontanum. E. W. Ruggles.
A Simple Method of Viewing Röntgenograms in Three Dimensions. M. Girsdansky.
A By Result of the Administration of Salvarsan. D. W. Montgomery.

Surgery of Myopia.—G. W. Vandegrift concludes that *ablatio lentis* must not be done in myopia of less than sixteen diopters. Success depends largely upon the youth of the patient and state of health of the eyeball. Extensive degeneration of the tunics of the eye, particularly in the macular region, contraindicates operation. The danger of detachment of the retina is only slightly, if at all, increased by operation. The progress of myopia and macular disease is not necessarily checked. Discission, single or multiple, in childhood; discission and linear extraction in the adult; and primary extraction after the lens nucleus has become sclerosed are the operative procedures of choice.

Full Term Ectopic Gestation.—E. McDonald presents a study of this subject. The chief difficulty in the later months is to differentiate the condition from normal pregnancy. The gravid tumor develops beside the uterus, which is pushed to one side. There is a retrouterine fulness, and the head or breach cannot infrequently be felt through the vagina. If the child is transverse, the retrouterine fulness will be found to fluctuate. The cervix is commonly enlarged and softened, but not to the extent of a normal pregnancy, and will be found to be harder and firmer than the duration of a normal pregnancy would allow. The history of the passage of decidua and the presence of the small uterus aid in the diagnosis. The use of the sound is justified when the uterus is plainly felt, but it should be remembered that normal pregnancy is most frequently mistaken for this condition.

Defective Memory in Brain Syphilis.—C. W. Burr reports the case of a man who at the age of twenty-three had an initial lesion, underwent treatment for two years, and four years later developed brain syphilis, including convulsions, hemiplegia, and aphasia. Under treatment he recovered with the exception that he was left with a defective memory.

Palpation.—M. I. Knapp describes a method of palpating the abdomen, with the patient in a slanting position with the head down. The examiner stands at the head of the patient and, using the fingers lightly flexed, gently palpates the abdominal organs, which are relieved of the tension of the abdominal wall.

Reduction of Infant Mortality.—By S. J. Baker. (See MEDICAL RECORD, October 21, 1911, page 849.)

Disease of the Verumontanum.—By E. W. Ruggles, (See MEDICAL RECORD, October 7, 1911, page 747.)

Röntgenograms in Three Dimensions—M. Girsdansky presents a concluding report on his simple method of viewing röntgenograms in three dimensions.

A By-Result of the Administration of Salvarsan.—D. W. Montgomery and G. D. Culver report the case of

a man who for twenty years had suffered from hyperkeratosis of the soles of the feet. On the theory that this might have been of syphilitic origin, he was given while in Europe two injections of salvarsan into the buttocks. These left hard indurations, one of which broke down, with the formation of a fistula discharging blood serum and shreds of necrotic tissue.

Woody Phelgmon of Reclus. E. J. Pantzner.
A New Medicine-Dropper Clip. P. R. Wood.

Disturbances of Respiration Due to Nuclear and Infranuclear Disease.—C. F. Hoover calls attention to the nervous disturbances of respiration occurring after small doses of morphine in certain diseases: tabes dorsalis, sclerosis of brain arteries, tuberculosis of the mediastinal lymphnodes, and aneurysm of the first portion of the aorta. Some years ago he had reported such disturbances (loss of consciousness, cessation of breathing, vasomotor relaxation) calling for active artificial respiration, and in one case, which he mentions, ending fatally. The tolerance for morphine was regained after the disease had progressed. In tabetic cases the process is limited to the bulbar nuclei and is not associated with disturbances in the higher cerebral structures such as occur in arteriosclerosis. The practical point is that one should be very cautious in the use of respiratory depressants when there is any reason for suspecting degeneration in the respiratory center, but impulses from the cerebral cortex may share in the respiratory symptoms, which have been attributed solely to changes in the bulbar center.

Drainage in Pelvic Infections.—By L. G. Bowers. (See MEDICAL RECORD, July 8, 1911, page 105.)

Vaccines in Pelvic Infections.—By J. O. Polak. (See MEDICAL RECORD, July 8, 1911, page 105.)

Alcohol and Drug Habitués.—D. Crosby advocates state control of drug and alcohol habitués. If one will estimate the tremendous cost of present methods, jail and police court expenses, and maintenance of inebriates in public hospitals and almshouses, one can easily gather data to show the taxpaying public the economic value of the cure of curable and the control of incurable drug and alcohol habitués.

Chronic Alcoholism.—G. E. Pettey states that probably 80 per cent. of all habitual drinkers form the habit inadvertently and unintentionally. A small percentage of persons are born with or have acquired in early life from disease a defective physique and an unbalanced nervous system, leading them to become ready victims of the seductive influence of alcohol. A third class includes a relatively small portion of regular drinkers who drink as a pure dissipation, having no moral fiber whatever and who would return to the use of alcoholic drinks even if cured. Dipsomania, or the imperative impulse to drink at some periods, would be better defined as periodic insanity taking the form of an uncontrollable desire for alcohol. In a majority of these cases the attack occurs only when the individual is excited by an added systemic derangement, an acute intestinal trouble, or autotoxemia. Another, and probably the most hopeless, class of periodic drinkers are the moral cowards who deliberately take to drink as a refuge from evils which they have not the manhood or moral courage to resist otherwise. In another class the sprees are due to bad environment coupled with instability of character. These are the social drinkers who lose control of themselves when one drink has been taken, but who in better environment and out of temptation would remain sober. Still another type are those who have an inherited or acquired craving for liquor, which they resist under ordinary conditions but succumb to when in bad associations or under temptation. These are the most amenable to treatment.

Inoculation Against Typhoid.—K. Nelson and W. E. Hall describe the methods of antityphoid inoculation used by them in the Eighteenth United States Infantry Regiment. Thirty-five hundred separate inoculations were made. Two hypodermic syringes and six separate needles were used, the needles being sterilized after each inoculation. There was not in the whole number a single case in which the temperature rose to 102°, and there was no suspicion of infection or ill effect which could be attributed to the vaccine. Care must be taken to give the vaccine subcutaneously and not intravenously. In the one case in which this latter occurred the reaction lasted three days, though the local reaction did not appear. In the 12,000 men in the encampment at San Antonio there was but one case of typhoid fever, and that was in a civilian teamster who had never been inoculated against typhoid.

Acute Thyroiditis.—H. V. Dutrow reports a case of idiopathic, non-purulent acute thyroiditis occurring in a male laborer thirty years of age.

Foreign Body in Intestine.—E. H. Moss reports the case of a maniacal female patient aged twenty-seven years who swallowed a mass of rope, her gown, bed sheeting, and hair. Ten months later this mass, which weighed two and a half pounds, was passed per rectum.

Woody Phlegmon of Reclus.—E. J. Panzner reports a case of this condition in a woman aged twenty-five years. Following an attack of pharyngitis, a boardlike mass developed in the cervical region. The mass was hard except for a small fluctuating area. There was no pain, no rise in temperature, nor dyspnea. One month later pus was evacuated. During the following four months pus flowed from several small sinuses, the mass became smaller and softer, and finally disappeared.

Medicine-Dropper Clip.—P. R. Wood has devised a clip which may be attached to the side of a bottle and which has two loops, the top one sufficiently large to engage loosely a pipette of any size, while the lower one engages and supports the tip.

Recent Developments in the Recognition, Treatment, and Prophylaxis of Syphilis. H. C. French.
Colotomy and Some Misconceptions of Its Results. P. Daniel.
The Differential Diagnosis of Syphilis and Parasyphilis of the Nervous System. F. W. Mott.
A Sphygmographic Method for the Estimation of Systolic and Diastolic Blood Pressure. J. D. Windle.
Preliminary Report on the Treatment of the Vaccination Site with Picric Acid Solutions. J. F. Schamberg and J. A. Kolmer.
A Note on the Cerebrospinal Fluid in Acute Poliomyelitis. J. G. Forbes.
Rupture of the Popliteal Artery and Vein: Diffuse Hematoma. D. Drew.
Two Rare Abnormalities Observed in the Course of Operations. J. D. Malcolm.

Treatment of Syphilis.—H. C. French advocates the early injection of salvarsan to expedite the healing of primary lesions, followed by a course of mercury, which he believes is the real curative agent.

Colotomy.—P. Daniel states that the supposed disabilities arising from a colotomy are loss of the sense of desire to defecate—*i.e.* warning; excessive number of actions—*i.e.* diarrhea; loss of control over defecation; excoriation of the skin; the wearing of an apparatus; and the presence of an artificial anus on the abdomen. The last two are inevitable, but in practice they are really the least

of the evils. If the surface of the colon is healthy—*i.e.* free from colitis—the débris of the food will gradually collect and remain in the sigmoid until sufficient bulk has accumulated to excite the normal peristaltic action, when an evacuation occurs. This bulk of stool usually represents in the normal patient the food débris of the preceding twenty-four hours; hence a second action should not be necessary, or possible even, for another twenty-four hours. If there is no oral sepsis or sepsis due to accessory sinus disease there is no diarrhea. Regulation of the diet permits of control of defecation.

Syphilis and Parasyphilis of the Nervous System.—By F. W. Mott. (See page 1193.)

Systolic and Diastolic Blood Pressure.—J. D. Windle describes a method of estimating these by means of the Mackenzie ink polygraph and the Riva-Rocci blood pressure apparatus.

Treatment of Vaccination Site.—J. F. Schamberg and J. A. Kolmer find that the use of a 4 per cent. alcoholic solution of picric acid upon the vaccinated area forty-eight hours after the insertion of the lymph does not interfere with the success of the vaccination. This treatment lessens the degree of the local inflammatory reaction. The patients are not so apt to exhibit constitutional disturbance. The epithelial covering of the vaccine lesion is hardened, and there is a decreased liability of extraneous bacterial infection. This is doubtless due in part to the antiseptic properties of the solution applied. Picric acid is about four times as efficient as phenol as a local antiseptic. The common organisms on the skin are lessened in number by the application of solutions of picric acid.

Cerebrospinal Fluid in Acute Poliomyelitis.—J. G. Forbes reports the results of the examination of the cerebrospinal fluid in thirty cases of poliomyelitis. The relation between an increase in amount of albumin and the presence of lymphocytes in excess appears to be fairly constant, and may reasonably be taken as evidence of tissue reaction in the presence of the hitherto unrecognized virus—a reaction shown in sections, by the perivascular lymphocytic infiltration in the substance of the cord, and also seen in the spinal meninges.

Rupture of Popliteal Artery and Vein.—D. Drew reports a case of this condition caused by trauma and resulting in the formation of a hematoma which was subsequently infected.

Abdominal Abnormalities.—J. D. Malcolm reports a case of the presence of the colon all on one side of the abdomen, which condition was discovered during an operation for appendicitis. He also reports a case of the shutting off of the small intestine from the general peritoneal cavity by a peritoneal membrane. This anomaly was discovered during an operation of gastrojejunal anastomosis for secondary cancer involving the stomach.

November 7, 1911.

Ventricular Puncture for Relief of Intracranial Pressure.—Anton and von Bramann report 50 cases of this form of intervention. The technique is simple. The cranium is perforated just behind the coronary suture near the middle line. The exposed dura is then incised, taking care to avoid a vein. A curved cannula is then passed along until it abuts against the falx cerebri. Using the latter as a guide, the cannula is now directed downward until it pierces the roof of the ventricle. As a rule from 10 to 30 c.c. of fluid are withdrawn, but in large hydrocephali from 50 to 70 c.c. may require withdrawal. The procedure is useful in congenital and acquired hydrocephalus, tumors of the hypophysis and organs adjacent to the ventricles, and in some tumors elsewhere in the brain. In many cases puncture serves as a prologue to a radical operation for extirpation of tumors. Puncture first relieves the tension on the roof of the lateral ventricles. A communication is opened between the ventricular cavity and the subdural space, and this opening may remain patent for months if desirable. By using the sound a passage may be opened between the third and the other ventricles. This is often desirable, as the third ventricle may be much distended with resulting prejudice to the subjacent optic chiasm. The puncture renders great service in preventing choked disks if there is any reason to suspect the existence of a tumor or cyst of the fourth ventricle.

Treatment of Frambesia with Salvarsan.—Flu of Dutch Guiana has treated 700 cases of yaws with salvarsan. The results are not only better than those obtained even in syphilis, but, according to the author, we have for the first time a true remedy for the former. This seems to imply that mercurials and iodides have not been very successful in the treatment of yaws as a folk plague. Concerning the relation of yaws to syphilis, this seems puzzling. A large number of manifestations are common to both diseases, so that a diagnosis from these alone would be impossible. It is possible but not necessary to divide yaws into primary, secondary, and tertiary. The primary lesion or mamma yaw may occur on the penis or vulva, but this is the exception. As a rule it comes on the foot. In children it may occur on the lips and groins, and in nursing women on the nipple. Like the primary syphiloma, it may begin as a papule, but when fully developed it occurs as an ulcer with undermined edges and lardaceous flow. The center may granulate and the border become elevated and wall-like. There is no mention of anything like the typical Hunterian chancre nor of a typical adenopathy. The most common secondary manifestation is a small papular exanthem, which, like its syphilitic analogue is persistent for a long time. Another form is seen in the raspberry-like lesions which originally gave the disease its name or names. The so-called crab-yaws are analogous to the palmar and plantar syphilides and ringworm yaws resemble serpiginous syphilides. Common in yaws but rare in syphilis is effusion into joint cavities.

Habitual Constipation and the Urinary Organs.—Asch calls attention to the fact that in habitual constipation several types of reaction affecting the urinary system may be recognized. The first is purely mechanical, due to the pressure of impacted feces on the bladder and prostate. The symptoms consist of desire for urination, phosphatic urine, and partial retention. The soft catheter may bring away as much as 3 liters. The syndrome is doubtless due to an acquired dystopia of the bladder. In a second group of patients, neuropathic and suffering doubtless from spastic constipation, the symptoms include vesical tenesmus, headache or migraine, listlessness, etc. This syndrome is ascribed to congestion of the pelvic viscera which is often augmented by the habitual use of purgatives. In the third group there is a coli bacilluria of intestinal origin. The patients may have albuminuria and cylindruria, leading to a false diagnosis of nephritis.

Deutsche medizinische Wochenschrift.

November 9 and 16, 1911.

Diagnosis of Sudden Plugging of the Coronary Arteries.—Hochhaus recently made the correct diagnosis in four cases, confirmed by autopsy. The first subject was an aged invalid who, however, had never presented cardiac symptoms. He was seized with precordial pains and dyspnea of severe character, becoming worse. Pulse very rapid, hardly palpable, but regular. Heart sounds very low, no palpable impulse. There were associated nausea, vomiting, and tympanites. The diagnosis was promptly made. Autopsy revealed thrombosis of the coronaries.

There was a high degree of arteriosclerosis. The left ventricle was much hypertrophied Most of the other finds seem to have been secondary to the closure of the coronaries, as the patient had lived five days after the sudden onset. He yielded only slightly to cardiac stimulation. The second case was in a much younger man (53) with a history of chronic cardiac disease. The symptoms were much the same as in the first case. Autopsy showed long standing sclerosis of the coronaries, which were closed by thrombosis. The heart was greatly hypertrophied and dilated. The diagnosis had never been in doubt as the history pointed plainly to coronary sclerosis (frequent attacks of precordial pain and dyspnea before the fatal attack). The third case, on the contrary, simulated pneumonia at the outset. There was no history of cardiac symptoms in the 54-year-old male patient. The correct diagnosis was apparent as soon as the patient was under observation, when the regional pain, dyspnea, and cardiac weakness were such as to preclude any other opinion. The fourth patient was an old woman, very stout, with a complication of diseases. The diagnosis was made through the sudden, persistent, and increasing type of precordial pain and dyspnea.

Improved Technique of Cesarean Section.—Freund has of late years modified his previous views until he recommends the following manual of procedure as far as the classic abdominal operation is concerned. The uterine incision is carried as deeply as possible downward in the anterior wall. That is, it is removed as much as possible from the fundus in order not to encounter the placenta. The danger of adhesions is also reduced to a minimum. If the uterus contracts the deepseated scar should form a concavity. The serosa should not be embraced in the deep uterine sutures, lest the proper union of the muscular planes be interfered with and a rupture occur during subsequent labor. Silk should be used for deep sutures, catgut for superficial ones. Small, frequently repeated doses of ergot should be given after the operation.

Mixed Inspection in Pulmonary Tuberculosis.—Kögel states than in 40 tests on 17 subjects he found hemolytic staphylococci in 5 cases only while hemolytic streptococci could not be found at all. In but one of the five cases with positive find was the disease a mixed infection from the clinical standpoint, although otherwise the type of disease was severe. The blood was invariably sterile. In five cases of cavernous phthisis ordinary anaerobic streptococci were present in the sputum. The author has become sceptical as to mixed infection. While it doubtless occurs, it can hardly be regarded as frequent. He concludes that the anaerobic cocci originally present in the lungs as saprophytes may by thriving in the diseased tissues develop hemolytic qualities.

Indications and Technique of Douche Therapy.—Brieger restricts the word douche to hydrotherapeutic procedures applied externally for heat and cold effects. Air and steam douches are also considered. The field of activity for these procedures is so extensive that a mention of contraindications is of more significance than the counter enumeration. These are advanced heart and lung diseases, atheroma of the arteries, and conditions of excitement. One should also avoid the head douche in arteriosclerosis, and the abdominal douche in pregnancy. It must also be borne in mind that habitual douching may increase nervousness, while it may further be followed in the aged by myalgias and neuralgias. Most of the uses of the various douches are old, but the alternating air douche, operated by a motor, has of late years had a good deal of vogue in rheumatoid and neuralgic complaints and skin diseases. The interrupted cold douche is extensively employed in congestions and atony of the abdominal viscera. The enlarged spleen of malaria may thereby be reduced in size.

Origin, Nature, and Significance of Fever.—Rolly begins an article on the subject and first discusses the fever syndrome. Rise in temperature is the most constant and characteristic symptom, but this may occur independent of fever, and a "fever" without temperature rise is theoretically possible. Nonfebrile pyrexia is usually spoken of as neurogenous and may be studied experimentally in the so-called puncture hyperthermia, caused by puncturing the corpus striatum in rabbits. The author was able to demonstrate that the temperature rise in such cases is due to increased glycogen metabolism. In true fever the cause is an infection. Both types of pyrexia are attended by increased metabolism. If no essential difference can be detected in the two, then one might be justified in believing that the toxin of the infectious process simply acts upon the nerve centers and that in both cases temperature rise is neurogenous. But the author has been able to show that a fundamental difference does exist, as follows: In infectious fever the toxin present causes a disintegration of tissue albumin, and this is in turn the cause of the pyrexia, which again sets up more metabolism. In neurogenous fever there is no initial disturbance of protein metabolism.

Free Arthroplasty.—Hinz, in connection with resection of both articular surfaces of a tuberculous kneejoint, replaced the diseased tissues with homologous material from a man dead of gunshot wound. There was some disparity in size, the structures from the cadaver being larger, which necessitated trimming them freely. The operation, while tedious, was successful and healing smooth enough. The second change in dressings showed a joint fistula which gave vent to a little serum only. The *x*-ray showed good position of the implanted structures, but a certain amount of crepitus showed that something was wrong and the fistula began to secrete pus. Believing that the segments had failed to heal in, an exploratory incision was made and the author was surprised to learn that the bone had united, the necrosis being confined to the cartilaginous surfaces. The purulent discharge gradually lessened and patient was placed in a walking splint. The discharge returned and there was no longer a doubt that the transplanted femur had become necrotic. A second resection was then done and all the transplanted tissues removed.

Treatment of Phlegmonous Inflammation of Waldeyer's Ring.—Winkler regards as a single infection with variations in location the following conditions: Tonsillar abscess (quinsy), retropharyngeal abscess, and phlegmon of the lingual tonsil. The nature of these processes is obscure, and we do not know why in a given case there should be a particular location in one portion of the ring. Although in retropharyngeal abscess the pus may burrow downward and point in the neck, the author does not apparently see any necessary connection between the suppurations in Waldeyer's ring and the other series of phenomena known collectively as Ludwig's angina, in which the primary foci of disease are in the floor of the mouth, lower pharynx, etc. He does not even allude to these lesions. Owing to the danger of recurrence and reinfection none of the suppurations should be treated with mere incision alone if it be possible to extirpate the entire focus of disease. While the tonsillar abscess may be reached handily through the natural passages, the other forms most commonly require attack through the neck.

Adrenalin in the Blood During Pregnancy.—M. Neu has found that adrenalinemia occurs during pregnancy, parturition, and the puerperium. The highest content in adrenalin was found in the serum obtained from a retroplacental hematoma and from the blood of the umbilical cord. The author suggests that adrenalin may be the immediate exciting cause of the uterine pains.—*Medizinische Klinik.*

Insurance Medicine.

DENTAL DISEASE AND LIFE INSURANCE.

Within recent years the clinical significance of diseased conditions in the mouth has forced itself more and more upon the attention of internists. The medical profession, particularly in England, has perceived more than a fancied connection between diseases of the teeth and pathological conditions of other organs. Pernicious anemia and gastric ulcer, to say nothing of the numerous disturbances of digestion and of metabolism, have been attributed by various observers to dental disease. It is unfortunate that until the present time the practice of dentistry has been divorced from the sphere of the general practitioner. This separation has prevented the timely recognition of the important rôle played in human pathology, by diseases of the teeth. This subject is admirably presented in a small volume just issued, from the pen of J. F. Colyer, with the assistance of S. Colyer.* In a manner indicative of their complete mastery of the subject, these observers describe normal and pathological dentition, the conditions which influence the growth of the jaws and the formation of the teeth, the pathology of dental caries, the diseases of the pulp tissue of the periodontal membrane, of the gums, and adjacent mucous membrane. The subject of oral sepsis and its influence on the body is one which will repay careful study by the general practitioner. Septic absorption from the teeth gives rise not only to local conditions in the upper respiratory tract, such as infection of the tonsils and chronic pharyngitis, but also to lymphadenitis, which is frequently tuberculous. Less frequent, though not less important, are the secondary infections caused by the passage of the infective material along the natural ducts. These secondary infections may be enumerated as follows: Septic gastritis, enteritis, and colitis, parotitis, pancreatitis, and septic cholangitis. In addition there are conditions due to the continuous passage of bacteria or toxins directly into the tissue. To this toxemia is attributed by Hunter the production of septic anemia and of pernicious anemia. Other observers have beheld in oral sepsis a potent cause in the production of certain cases of neurasthenia, neuritis, and even degeneration of the spinal cord. Recently a close connection has been traced between arthritis deformans and septic conditions in the mouth. In addition infective endocarditis and septicemia and pyemia have in many instances been traced to infection from the teeth.

The bearing of these facts upon the problems of life insurance is obvious. Indeed, the authors devote an entire chapter to this subject. They point out that the relation of dental disease to life insurance has not received adequate recognition, and that in the examination of applicants very little attention is paid to the condition of the mouth. This is the usual practice in spite of the supposition that individuals with oral sepsis have a shorter expectation of life, although there are no figures upon which this conjecture may be based. The uncertainty as to future dental defects is greatest in the case of children in whom environment plays a greater rôle than heredity, which at any rate must be disregarded in the estimation of dental tendencies. It is pointed out that the insurance companies, in the protection of their own interests, in the insurance of children, make the premiums large enough to cover the maximum risk. Possibly in the case of individuals with healthy mouths too high a premium is paid. In the insurance of adults, although at the time of examination the mouth may be in a healthy condition, one cannot be certain that the individual will be free from dental disease in the future. Of practical importance to the medical examiner are the following facts: If at the age of 23 to 25 years there are no signs of dental caries or of periodontal disease (pyorrhea alveolaris) and if the individual is one who is presumed to have sufficient intelligence to care for his teeth properly, one may assume that a healthy mouth will be retained throughout life. If there is extensive caries but no periodontal disease careful treatment will render the mouth healthy and this may remain so. The presence of periodontal disease, however, presents another picture. Even if this disease is in its early stage, in the majority of cases, in spite of rigid care of the mouth, the disease will make headway. As to the age incidence of this disease, when it does appear it is almost invariably present before the age of 30 years and usually before the age of 20.

Of particular importance to the medical examiner is the fact that in its early stages periodontal disease frequently escapes notice for two reasons: The disease is not easily detected and it is not fully understood. The presence of this condition must be regarded as a focus of infection that may remain with the applicant for years, a constant menace to his general health. The insidious nature of the condition, and the fact that the teeth may appear sound although the gums are congested and the alveoli are the seat of suppuration should make the examiner hesitate to accept a risk before he has made a thorough examination of the teeth. If periodontal disease is present the applicant should not be accepted, at least not as a first-class risk, while the condition remains.

*Dental Disease in Its Relation to General Medicine. With Illustrations. London, New York, Bombay, and Calcutta: Longmans, Green, and Co., 1911.

THE EVIL EFFECTS OF A MULTIPLICITY OF EXAMINERS.

Many requests for appointment as examiner are received by life insurance companies from physicians whose standing and qualifications are beyond all doubt. The companies are not in a position to avail themselves of the valuable services offered if they are already fully represented in the particular localities in which these physicians reside. The reluctance to make additional appointments may seem unreasonable to some in view of the fact that such action would not increase the expense account, and it is, therefore, the object of this brief article to offer a word of explanation.

It is the custom of nearly all life insurance companies to limit the appointment of medical examiners to the smallest number consistent with efficient service. It has been found that, generally speaking, one examiner can easily take care of all the examinations when the number of inhabitants in the community does not exceed one thousand. If the population is more than one thousand, two examiners are quite enough except in the larger cities. When this rule is rigidly observed, it works admirably in the interests of both the company and the examiner for the following reasons.

1. When there is a multiplicity of examiners, the agent, if he happens to be over-anxious or unscrupulous, has too much latitude and, as a result, it lies in his power to select one examiner to the exclusion of the others for looking over his cases. This arrangement lasts as long as the favored examiner recommends the risks for acceptance. Poor risks are sure to turn up, however, and very soon the examiner must make an adverse report or become derelict in his duty. The erstwhile cordial grasp of the agent, as well as all examinations, and then diverted to examiner number two, and so on through the list. In this way an agent can hold a threat, open or veiled, over the head of the examiner whose services are sought for the time being, a condition at once intolerable to the company and the examiner and which is practically impossible when the number of examiners is properly limited.

2. A company looks for and usually gets good service from its examiners and in return the position of examiner should be kept as remunerative as circumstances permit. This object can be attained by a steadfast refusal on the part of the company to appoint examiners in a district where there is already a full complement.

Syphilis and Parasyphilis of the Nervous System.—F. W. Mott states that the curve of incidence of onset of syphilitic affections of the nervous system reaches its maximum somewhere between 25 and 30, whereas the curve of the incidence of onset of general paralysis and tabes reaches its maximum between 35 and 40. Whereas, on the one hand, syphilis of the nervous system produces more or less sudden obtrusive symptoms indicative of gross lesions due to meningeal irritation and vascular occlusion of a random, kaleidoscopic character, with remissions and exacerbations causing new and variable paralytic and irritative phenomena; on the other hand, parasyphilitic affections are usually so insidious in origin that it may be difficult to fix the date of the onset. Syphilis of the nervous system, especially in the early stage, yields to treatment, while parasyphilitic affections are seldom arrested. The neurasthenia occurring in the secondary or active stage of syphilis is not characteristic in its symptoms. It is of importance to diagnose between the headache of such an induced neurasthenia and true syphilitic headache of the secondary period. In neurasthenia there is little real pain, while in syphilitic disease the pain is intense, lancinating, boring, tearing. Neurasthenic headache is generally diurnal and worse in the morning on arising, while syphilitic headache is worse at night. It is important to distinguish the neurasthenic state from tabes dorsalis in the early preataxic stage, when the knee-jerks may be present, and from general paralysis in the preparetic stage. The parasyphilitic affections may be definitely differentiated from neurasthenia by an examination of the cerebrospinal fluid. In the former conditions there is even in the earliest stages a lymphocytosis in the cerebrospinal fluid, which also shows in about half the cases of tabes and in practically every case of general paralysis a positive Wassermann reaction. Hysterical paralysis and hysteroepilepsy sometimes occur in the secondary stage of syphilis and the symptoms disappear under antisyphilitic treatment. Syphilis is one of the most important factors in the production of arteriosclerosis and Bright's disease. Chronic alcoholism and syphilis are often associated. There is no clinical symptom or group of symptoms characteristic of syphilitic disease of the spinal cord, but there are certain symptoms which, if they occur in young adults, particularly of the male sex, should lead one to suspect their specific origin. The early symptoms are spinal irritation, severe intercostal pains, worse at night, cramps, and contracture of the limbs, with pains radiating down them, bladder disturbances, disappearance and reappearance of the knee-jerks, the Brown-Séquard phenomenon; in fact, symptoms pointing to a local or more generalized meningitis or meningomyelitis, but usually without pyrexia unless there be some complication. As in cerebral syphilis, so in the spinal disease, the symptoms are particularly liable to remissions and regressions.—*Lancet*, November 18, 1911.

The Conservation Movement in Life Insurance—President W. A. Day of the Equitable Life Assurance Society has inaugurated a conservation department and has placed at its head E. E. Rittenhouse, former Commissioner of Insurance of Colorado. Regarding this new department, the following statement has been given out: "All life insurance companies suffer from two sources of waste or loss, which have been given much study and which continue to cost the policy holders large sums annually. One is the annual loss of life from preventable or postponable causes. The other is the loss due to the costly American habit of lapsing policies. The life companies of the country lost from this source last year over $700,000,000 of insurance already on their books, which cost the policy holders of the United States over $20,000,000 to put on the books. Our 25,000,000 policy holders are therefore personally and financially interested in the reduction of the loss from both these causes." In a recently published interview Mr. Rittenhouse pointed out the ways in which the insurance companies can join hands with government, state, and municipal authorities in lessening the waste of life, a waste estimated at the sacrifice of 600,000 lives annually in the United States. Through their enormous constituency of 28,000,000 people, it is hoped that the life insurance companies will awaken the public interest in measures for improving the health of the people, and that the latter will bring influence to bear upon their representatives for the enactment of health legislation. The national government should limit its activity to an educational campaign, while the State should carry on its work in two directions, first, the distribution of health bulletins, and the liberal use of medical inspectors; second, the provision of free medical examination periodically to any who may desire it for the purpose of detecting disease in time to check or cure it. Those who could afford it would doubtless prefer to go to their own physician for periodical examinations, and the fact that the state thought it necessary to conduct such a movement would induce many thousands of them to do so. Until the plan was well understood the applications for free examinations would not be very large, but they would come from the poor and the very poor—those that know the least about avoiding disease and are most exposed to it. Thus the benefits of free examinations would go directly to the very element of our population which is most in need of them. In addition to this indirect influence which it will bring to bear upon the authorities, the insurance company will carry on an educational campaign among its policy holders, will cooperate in the teaching of hygiene in the schools, and possibly will provide a system of traveling lecturers. It will begin a policy of providing periodical examinations for its policy holders. It will probably maintain a staff of sanitary experts which will be subject to the call of any community that wants advice. There are many small towns and cities which wish to institute modern methods of sanitation, but which are not able to employ experts. These will be the communities that the company will be able to assist. Any community that makes the request will have an expert sent to it immedately. The expert will look over the sewerage system, the water supply, garbage disposal, and the inspection of milk, meats, and perishable provisions. This expert, if he finds unsanitary conditions prevailing, will give advice as to how to remedy them. It is possible that the mortality statistics will be watched, and, if an unusual death rate is found prevailing in any community, an expert will be sent to the locality to look over the situation.

A State to Write Life Insurance.—The Wisconsin Legislature of 1911 passed a bill providing for a system of life insurance by the State. It is announced that the Insurance Commission is now drawing up forms for policies and as soon as these are ready the county officials will begin to accept risks.

Book Reviews.

THE MEDICAL RECORD VISITING LIST, OR PHYSICIAN'S DIARY FOR 1912. New Revised Edition. Price $1.25 (30 patients), $1.50 (60 patients). New York: William Wood and Company.

THE main portion of this pocket volume contains ruled blanks for daily visiting list, consultation practice, obstetric engagements, record of obstetrical practice and of vaccinations, register of deaths, addresses of nurses and patients, and cash account. It also contains much valuable information, such as treatment of poisoning and other emergencies, artificial respiration, signs of death, and tables of drugs and preparations with dosage. It is printed on good paper, suitable for either pen or pencil, and is handsomely bound in leather. The volume is useful and attractive, and is of convenient size.

THE CONCISE OXFORD DICTIONARY OF CURRENT ENGLISH. Adapted by H. W. FOWLER and F. G. FOWLER, authors of "The King's English," from the Oxford Dictionary. Price, $1.00 net. Oxford: At the Clarendon Press; New York: Henry Frowde, 1911.

THIS is a wonderfully complete and useful little dictionary, partly encyclopedic in character, founded upon the great "Oxford English Dictionary." The word "little" is used solely to note the size of the book, a duodecimo of 1,041 pages, but "great" more properly characterizes its contents. Its vocabulary, limited as the title states to current English, is enormous, and contains, as the reviewer has learned by a painstaking thumbing of the book in reading a number of works of the most varied character (not medical), nearly every word that any reader of modern English is likely to encounter. In order to condense such a mass of material into so small a space it has been necessary to resort to special type and diacritical marks, which are at first sight confusing, but which become intelligible enough after a careful reading of the explanatory prefarce.

The spelling is more "American" than we would expect to find in an English work. The *our* in the termination of words such as honour and favour is indeed retained, although the Oxford Dictionary gives *or* as permissible, but the suffixes *-ize* and *-ization* are given in place of *-ise* and *-isation*, and words such as judgment are given with this spelling in preference to judgement. The automobilist, whose eye is often strained by the *tyre* of English books and journals, will be pleased to find that this dictionary prefers the eminently correct *tire*. The final consonant is not doubled in derivatives of verbs such as *rivet* and *level*, though the editors balk at *traveler* and give only *traveller*. They frankly acknowledge their inconsistency in this spelling and in the varying use of the hyphen in compounds, confessing their inability to do aught than "welter in the prevailing chaos." In the etymology the Greek words are written with Roman characters, the fact being recognized that the great majority of users of the dictionary are unable to decipher the Greek letters.

The convenient size of the book, the wealth of the vocabulary, the mass of information compressed into small space, the authority of the Oxford Dictionary upon which it is founded, and the concessions to American usage will doubtless make this, as it deserves to become, a popular dictionary for all users of the English tongue.

AMERICAN POCKET MEDICAL DICTIONARY. Edited by W. A. NEWMAN DORLAND, M.D., Editor "Dorland's American Illustrated Medical Dictionary." Seventh Edition. Flexible leather. Price, $1.00 net; thumb indexed, $1.25 net. Philadelphia and London: W. B Saunders Company, 1911.

To those who are content to use a condensed dictionary, with its necessarily unsatisfactory definitions and omission of much of the information that a dictionary should contain, this little book will commend itself as by far the best of its class. It is evidently the work of the editor himself and not a compilation by some unknown person put forth under the editor's name, and the definitions come as near being real definitions as is possible in a work of this kind.

THE PRACTITIONER'S VISITING LIST FOR 1912. Thirty Patients per Week. Price $1.25. Philadelphia and New York: Lea and Febinger.

THIS well-known visiting list, the successor of the *Medical News* Visiting List of former days, needs no detailed description. In addition to the blank pages for the record of visits and charges, the book contains a scheme of dentition, a table of weights and measures, instructions for urinary examination, a diagnostic table of the eruptive fevers, a dose table, an index of diseases and their remedies, illustrated directions for the ligation of arteries, and other useful information.

KLINISCHE PATHOLOGIE DES BLUTES NEBST EINER METHODIK DER BLUTUNTERSUCHUNGEN SPEZIELLER PATHOLOGIE UND THERAPIE DER BLUTKRANKHEITEN. Von Dr. ERNST GRAWITZ, Professor an der Universtät zu Berlin, Dirigierender Arzt der inneren Abteilung des städtischen Krankenhauses Charlottenburg-Westend. Mit 45 Figuren im Text, 6 Tafeln in Farbendruck und einer Tafel mit Mikrophotogrammen. Vierte vollstandig neu bearbeitete und vermehrte Auflage. Price, 30 marks. Leipzig: Georg Thieme, 1911.

THE fourth edition of the well known clinical pathology of the blood by the late Prof. Ernst Grawitz appears in a very much enlarged form. It still retains the features which have made it welcome in all clinical laboratories, the exquisite colored plates, and the extremely practical and sane treatment of the subject matter. The first seventy-five pages are devoted to technical methods employed in the study of the blood. There has been some revision in this chapter, especially in the portion dealing with staining methods, and a good deal has been added on the technique of the determination of coagulation and viscosity. The paragraph on alkalinity does not, however, take into consideration our recent physicochemical knowledge of ionic equilibrium in complex fluids. The section treating of blood coagulation has been revised. In the chapter on the morphology of the leucocytes there is an interesting new plate showing various types of cells taken with ultraviolet light. The vexed question of leucocytosis occupies forty pages and represents quite accurately the knowledge of the present day. The rest of the book is taken up with a discussion of the alterations in the blood in disease. The author still holds to his personal view of the curability of pernicious anemia, though this is not generally accepted even by his own countrymen; but inasmuch as he does not regard the blood picture of pernicious anemia as in any way specific it is easy to see that many of the severe hemorrhagic anemias might be included under this name, and that such patients might by the simplest of remedies be brought back to health. Many of them, in fact, do well even with rest in bed so long as the hemorrhage is checked. The question, after all, like so many of our problems in medicine, is merely one of definition; in other words, a distinction between a large series of anemias and the true Biermer's anemia, which seems to have a definite clinical course and a characteristic blood picture. Except for this phase of the book the author's attitude conforms to that of the majority of specialists. He wisely avoids the endless discussions which are now going on, especially in Germany, in regard to the minute points concerning the morphology of the blood cells and the nature of so-called diseases of the blood. In this freedom from discussion of useless details the volume makes a strong appeal to the practitioner, and it is sad to remember that Grawitz has not lived to enjoy the appreciation which every one must give to this most excellent book.

BEITRÄGE ZUR DIAGNOSTIK DER INNEREN UND CHIRURGISCHEN PANCREASERKRANKUNGEN. Von Dr. ALBERT ALBU, in Berlin. Price 2.50 marks. Halle a. S.: Carl Marhold, 1911.

SINCE the appearance in 1898 of the monographs on diseases of the pancreas by Oser and Körte, although the knowledge of this subject has grown more precise and extensive, it has been treated quite sparingly in general textbooks. The present volume includes all that is known on this subject at the present day. The author, employing a style that is at once clear and condensed, is able to present this subject within the limits of 104 pages. Particularly complete are the sections on general or functional and special diagnosis.

PROCEEDINGS, CONFERENCE ON MILK PROBLEMS. Under the auspices of the New York Milk Committee, December 2 and 3, 1910. Price $1.00. New York: New York Milk Committee, 1911.

THE many aspects of the problems of supplying pure milk and of its relation to the public health are clearly focused in the discussions that are recorded in this volume. The conference comprised four sessions, at which the following topics were taken up: milk economics, the public milk supplies and the public health milk standards, and milk commissions. Each of these topics included a number of subsidiary themes, such as milk transportation, milk supplies of villages, laboratory milk standards, state regulation of milk prices, etc. This book should be within easy reach of every health officer and pediatrist.

Pubertät und Sexualität. Untersuchungen zur Psychologie des Entwicklungsalters. Von Dr. August Kohl. Price, 1.50 marks. Würzburg: Curt Kabitzsch (A. Stuber's Verlag), 1911.

This small volume of 82 pages deals with a subject that interests the physician no less than the psychologist and the pedagogue. The author introduces the first chapter with the following quotations from Stanley Hall. "Neither the psychology nor the pedagogy of adolescence can be treated without careful consideration of the whole problem of sex." The sexual instinct irradiates the entire physical and psychical life of man. The study of the genesis of this instinct and its development through the phases of unconscious and then of conscious sexuality is presented by the author in the scholarly manner characteristic of German writers on this subject.

Handbuch der Speziellen Chirurgie des Ohres und der oberen Luftwege. Herausgegeben von Dr. L. Katz, Spezialarzt für Ohren, Nasen, und Halskrankheiten in Kaiserslautern; Dr. H. Preysing, Professor der Ohrenheilkunde, ord. Mitglied der Akad. für Prakt. Medizin zu Cöln a. Rh.; und Dr. F. Blumenfeld, Spezialarzt für Nasen, Hals, und Lungenkrankheiten in Wiesbaden. I Bd., 1 Hälfte, Lief. 6, price 7 marks; 1 Bd., 2 Halfte, Lief. 1, price 6 marks. III Bd. Lieferung 1 und 2, price 12 marks. Würzburg: Curt Kabitzsch (A. Stuber's Verlag), 1911.

The broad scope of this work has been indicated in recent reviews in the Medical Record. The sixth instalment of the first half of the first volume contains the subject of the topographical anatomy of the ear, with the presentation of many superb colored plates. In the first instalment of the second half of this volume the treatment of stenosis is discussed by Professor Pieniazek of Cracow. The subject of prosthetic surgery of the region of the face and skull is begun by Professor G. Port. In the first and second instalment of the third volume there are presented the subjects of the surgery of the external portion of the nose, by Professor O. Seifert of Würzburg; and of the operations on the nasal accessory sinuses, by Professor Dr. Boenninghaus of Breslau.

Veterinary Bacteriology. By Robert E. Buchanan, Ph.D., Professor of Bacteriology in the Iowa State College of Agriculture and Mechanic Arts, Division of Veterinary Medicine: Bacteriologist of the Iowa Agricultural Experiment Station. Illustrated. Price $3.00. Philadelphia and London: W. B. Saunders Company, 1911.

This volume is a revision of lectures delivered by the author and should prove a valuable addition to the library of the veterinarian. The first portion of the book deals with the morphology of microorganisms, laboratory technique, and a very complete discussion of the various phases of immunity, anaphylaxis, etc., as they are understood today. In its second portion are found the descriptions of the individual organisms and a brief consideration of the diagnosis and some points in the treatment of the disease caused by each. A group system of discussion has been adopted, and while it is perhaps not entirely satisfactory has proved very serviceable.

The methods given for the enumeration of bacterial vaccines are both inaccurate at best and it is unfortunate that the author has not included the method which utilizes the Thoma-Zeiss counting chamber and a diluting fluid which stains at the same time. The protozoa are fully described and the section on the diseases produced by ultramicroscopic organisms is a very satisfactory condensation of our present knowledge in that subject. The work is made complete by the inclusion of a number of organisms which are pathogenic only for man.

Laboratory Manual of Physiology. By Frederick C Busch, B.S., M.D., Professor of Physiology, Medical Department, University of Buffalo. Second Edition. Illustrated. Price $1.50. New York: William Wood & Company, 1911.

The second edition of this book has been thoroughly revised in order to bring it into harmony with the changes which have taken place in the five years since the issue of the first edition. Devised as a substitute for the lesson slips used in many schools, it is well arranged for its purpose. The directions for the performance of experiments are concise and clear, and space is not wasted in the wearisome and useless description of ordinary laboratory apparatus. The plan followed is to give directions for the performance of an experiment and to follow these with a series of questions designed to point the way in which the student should direct his observation. In this manner is obviated, as far as possible, his ever-present tendency simply to memorize the results and to neglect the method and applications. Many of the experiments in the chapter entitled Digestion, Secretion, Absorption might have been omitted, coming as they do under the head of physiological chemistry, in which department they are more fully and carefully considered than is possible in a course in physiology. The inclusion of the experiments on the thyroid, pancreas, and suprarenal is particularly commendable in view of the increasing importance which these glands are attaining in modern medicine. The book is substantially bound so as to survive the hard usage of the laboratory.

Nostrums and Quackery. Articles on the Nostrum Evil and Quackery from *The Journal of the American Medical Association*. Part I, Quackery. Part II, Nostrums. Part III, Miscellaneous. First Edition. Cloth. Price, $1; with individual's name on cover, 25 cents extra. Chicago: American Medical Association, 1911.

Both physicians and intelligent laymen will find this book of great service as an educator. It is a daily experience for the doctor to be told of some marvelous cure wrought by some patent medicine, and unless he knows the composition of the stuff he can speak only in generalities against all quack remedies and the danger of using them by guess. With this book before him, however, he may find an account of the very preparation in question, or at least of "something just as good," with the chemical analysis showing either that the stuff is made up of materials as potent as water or that perhaps it contains some ingredients of an absolutely poisonous character. By putting the book in the hands of his credulous patient he may be able to stop the "sure-cure" lie before it has gone far enough in that town or social circle to be dangerous. The book is an excellent one for the table of the doctor's waiting room and may be obtained for this purpose with the physician's name in the cover, with an injunction not to take it from the waiting room.

Moto-Sensory Development. Observations on the First Three Years of a Child. By George V. N. Dearborn, Professor of Physiology in the Tufts College Medical and Dental Schools, Boston; of the Relations of Body and Mind in the Sargent Normal School for Physical Education, Cambridge, etc.; Author of "A Textbook of Human Physiology," "The Emotion of Joy," etc. Price $1.50. Baltimore: Warwick and York, Inc., 1911.

Very few observations have been made on the mental development of the child. Preyer's study is the most notable of these. The present volume represents a valuable scientific contribution to the literature of psychology, for the author has set down in chronological order and with interpolated remarks his observations of the various reactions, reflex and voluntary, of his own little daughter, during the first three years of her life. The observations of the infant's reactions on the first day are most interesting, these reactions indicating to the author that the kinesthetic sense-organs already are in action and well connected with the centers concerned with emotional reactions, and because of the prompt inhibition demonstrated, also with the cortex of the hemispheres. The studies of Petersen, recently referred to in the editorial columns of the Medical Record, have been carried out along similar lines. The first-hand observations made by the author and his pithy commentary serve to make this book a most valuable and interesting one to the student of psychology.

Handbuch der Hygiene. Herausgegeben von Prof. Dr. M. Rubner, Geh. Medizinalrat, Berlin; Prof. Dr. M. V. Gruber, Obermedizinalrat, München; und Prof. Dr. M. Ficker, Berlin. II Band, 2. Abteilung Wasser und Abwasser. Mit 111 Abbildungen und 3 farbigen Tafeln. Price 15 marks. Leipzig: Verlag von S. Hirzel, 1911.

This is the second section of the second volume of a work on hygiene of which the title "handbook" gives only a modest hint of its monumental character. This section deals with the subjects of water supply and sewerage, which subjects are exhaustively treated by Professors Kolkwitz, Spitta, and Thumm of Berlin; Professor Schmidtmann of Marburg, and Building Inspector Reichle of Berlin. The biological and technical aspects of water supply and sewerage form a distinct chapter in public hygiene. The developments in these subjects during the past two decades are clearly mirrored in this volume, which shows the painstaking regard for detail which is characteristic of German scientific writers. The book is well written and profusely illustrated and forms a valuable addition to the literature of public hygiene.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON OBSTETRICS AND GYNECOLOGY.

Stated Meeting, Held October 26, 1911.

DR. H. D. FURNISS IN THE CHAIR.

Two cases of Perplexing Diagnosis.—Dr. HERMAN J. BOLDT reported these cases.

CASE I.—This was a case of tuboovarian inflammation resembling ectopic gestation. The patient was thirty-two years of age, had been married three years, but was never pregnant. She presented herself on October 3, giving a history of atypical bleeding. She complained of pain in the left iliac fossa. There were a slight increase in the size of the uterus and some softening. To the left of the uterus an enlargement could be felt which was thought to be a distended Fallopian tube. Colostrum was present in the breasts. One symptom which Dr. Boldt's experience had taught him was important in the diagnosis of ectopic gestation was that pain was caused by moving the vaginal part of the cervix forward. If ectopic pregnancy existed this caused pain in the lower part of the rectum. At operation it was found that this patient had a small ovarian cyst, about the size of a walnut, with catarrhal salpingitis.

CASE II.—This case was one of tubal pregnancy with atypical symptoms in a woman twenty-six years of age. She consulted Dr. Boldt because of atypical bleeding which was thought both by herself and by a physician whom she had consulted to be due to an abortion. She had no other symptoms, not even the slightest pain. Examination revealed nothing pathological in the pelvis. The right adnexa had previously been removed on account of tubal pregnancy, according to the statement of the patient. After an intrauterine application the slight bleeding ceased. A short time afterward the patient again consulted Dr. Boldt and complained of dull pain on the left side at the site of the ovary, which was thought to be due to a mild ovaritis. The patient had suffered much pain during the night previous to consulting Dr. Boldt. Examination revealed nothing except that the pelvic peritoneum was sensitive throughout. While tubal pregnancy was suspected, nothing was said to the patient, as there were no definite objective symptoms. The patient was directed to secure a nurse and to go to bed and apply an icebag to the abdomen. Two days later she had another attack of pain and a physician called in made a diagnosis of ectopic pregnancy. The next afternoon when Dr. Boldt saw the patient there was no distension of the abdomen, but pressure in the left iliac fossa showed sensitiveness. There had been no attacks of fainting, no collapse, and no anemia. On the following day she for the first time showed the beginning of a hematocele in the left pelvic cavity. She now had pain when the vaginal part of the cervix was manipulated, but there was no distension. About two hours later an operation was performed and there were probably less than 100 c.c. of blood in the abdomen, including that which had coagulated. A small rent in the tube was found near the uterine cornu. No attempt was made to remove the blood, as experience had taught him that the less manipulation done in the abdomen, consistent with the conditions found, the better for the patient. The second day the patient suffered some from the absorption of the blood that had been left in the abdominal cavity, but these symptoms passed away in a few days. Usually all of these symptoms, elevation of temperature, accelerated pulse, thirst, nausea, vomiting ,and distension, disappeared after the intestines had regained peristalsis and a bowel movement had taken place. Salicylate of eserine was usually effective in these cases if no peritoneal inflammation was present; it should be given in doses of not less than one-fortieth of a grain subcutaneously, repeated at intervals of four hours, until four doses had been given. Dr. Boldt analyzed these cases to see if in the first case a diagnosis could have been made with certainty and, in the second instance, to see if the diagnosis could have been made at an earlier period, and concluded that in the first case it seemed perfectly reasonable to suspct tubal pregnancy, especially as the husband had had a specific urethritis; as to the second case physicians were too ready to curette such patients and there was no reason why they should be subjected to curettage when there was no change from the normal in the size, position, and consistency of the uterus, and if bleeding amounted only to spotting. The diagnosis of ectopic pregnancy under such circumstances was unjustifiable on the part of anyone not unusually expert. It was not justifiable to subject a patient to operation unless there was present more reason than the mere suspicion of ectopic pregnancy. In that class of patients where immediate operation was imperative there were objective symptoms that could not be mistaken, namely, acute anemia and an almost imperceptible pulse. An expert could also usually determine the presence of fluid in the abdomen. They occasionally read of making a diagnosis of ectopic pregnancy before the rupture of the tube, but it was a fact that in the greater number of cases there was no rupture of the tube, but tubal abortion took place. Furthermore, patients were not likely to consult a physician before the beginning of tubal abortion. Dr. Boldt thought that no one factor played as great a rôle in the etiology of ectopic gestation as gonorrhea. He did not recall a single instance of this kind where the husband had not at some time had a specific urethritis.

DR. SAMUEL M. BRICKNER said that no statement should be allowed to go from the Section on Obstetrics and Gynecology that the diagnosis of an extrauterine pregnancy was an easy matter. Gonorrhea was a constant etiological factor in extrauterine pregnancies, and 90 per cent. of the males would be found to have had this disease at some time or other. There might be found some malformation of the Fallopian tube, or a polyp, especially on the same side as the extrauterine gestation; again, there might be a reversion in the type of the tube, thus placing the origin upon a biological basis. In a great many cases it was absolutely impossible to discover an etiological factor for the extrauterine pregnancy except a preceding gonorrhea, and this statement should be accepted as a dictum.

DR. BOLDT did not believe that they could state positively that gonorrhea was a factor in the causation of extrauterine pregnancy. He believed, however, that it played an important rôle as an etiological factor.

Esthiomène and Secondary Elephantiasis Vulvae (Ulcus Vulvae Indurativum Edematosum).—Dr. ARTHUR STEIN and Dr. W. J. HEIMAN presented a patient, thirty-three years old, who had been married thirteen years. She had never been pregnant. Three years after her marriage her husband acquired what appeared to be gonorrhea and was supposed to have been cured. He denied any other infection. Shortly after this she noticed a painful discharge from the rectum which at times was bloody. She was treated for hemorrhoids, with some improvement in her condition. About six weeks ago she noticed a painless swelling about the anus. The external genitals became larger and harder. There was no pain on micturition. The constant secretion from the rectum continued to cause her annoyance. She was first seen in May, 1911; the lesions then involved an area from the mons veneris to an inch behind the anus, and about two inches laterally. The lesions over the mons veneris and labia majora consisted of pale, yellowish to orange-colored

macules, papules, and cysts, varying in size from a pinhead to a kidney bean. The lesions about the anus were fleshy, an inch or more in length, and so closely crowded as to mould each other by pressure. The labia were equal in size, enlarged, and in shape resembled a cucumber. They were movable and painless. The distribution of the lesions was shown by illustrations. The swellings of both labia covered over the introitus vaginæ. Now the cystic lesions had disappeared. The color was of a uniform dusky red, not yellowish. The distribution of the lesions was unchanged. There were a few small, superficial ulcers, but in no wise resembling those of tuberculosis or lues. The anus was completely concealed by the polypi. The rectal walls were covered with polypi and the periproctal tissue was indurated. The deductions to be drawn from this case were comparatively clean cut. There was a chronic disease characterized first by a destructive process, secondary to which there developed elephantiasis, lymphatic dilatations even to the point of cyst formation, and, finally, papillary hypertrophy or polypoid excrescences. The lesions were the manifestations of the chemical irritant contained in the discharge from her rectum and in the rectal stricture which was present, both being due to an earlier gonorrhea. Such a condition and process, at once destructive and hypertrophic, would correspond to what in recent years had come to be understood as esthiomène. In looking over the literature they found but one case that absolutely corresponded to the one they described. The patient was presented for examination. The first case in the literature, described by Tilbury and Calcott Fox in 1870, was one in which the lesions were located upon the perineum and the thighs.

Dr. Walter James Heiman said that he wished to speak of some points more or less dermatological in connection with this subject. There were three or four conditions which should be considered in the examination of cases of this type, and the first of these was condyloma acuminatum. This condition could be readily ruled out. There was another group of cases which was originally described by Tilbury and Calcott Fox in 1879 under the name of lymphangioma circumscriptum cutis. When the patient was seen for the first time the impression was that they had to deal with lymphangioma cysticum, or a circumscribed cystic lymphangioma. Upon a more careful study of the case they were unable to find any of the pathological features of this condition, and hence this diagnosis was ruled out. A diagnosis of esthiomène and secondary elephantiasis vulvæ was finally made, the excrescences appearing over the anus and gluteal regions. In the case described by Tilbury Fox the growths were found on the perineum. This was the only case in the literature in which this localization was to be found. It had occurred to Dr. Heiman that this might be the connecting link between lymphangioma and the type of esthiomène under discussion. The typical localization of the lesions of true lymphangioma were found to be around the shoulder girdle, the face, and occasionally on the tongue. In lymphangioma cysticum the cysts would be filled with a clear, limpid yellow fluid; the cysts varied in size from a pinpoint to a lentil. They were grouped in patches one to four inches in diameter. The bases upon which these cysts rested were non-inflammatory. Dr. Stein's case could not possibly be diagnosed as a circumscribed cystic lymphangioma. There were few clinical and no histological evidences characteristic of idiopathic cystic lymphangioma.

Prolapse of the Uterus.—Dr. William H. Wellington Knipe reported the case of a patient, fifty-four years old, who had had eight children and no miscarriages. After the birth of her seventh child she had a complete prolapsus uteri; this had been repaired at Bellevue Hospital. After the birth of her last child the prolapse recurred. In June, 1906, she came to Dr. Knipe for an operation for complete procidentia uteri and a supravaginal hysterectomy was performed with fixation of the cervical stump to the anterior abdominal wall, in conjunction with plastic work on the perineum. On account of the hard work she was subjected to the prolapse recurred at the end of two years and another operation was done, at which the remaining portion of the cervix, with the whole vagina, was removed. The cavity left was closed by a series of purse-string sutures, beginning at the upper part of the wound and ending at the introitus vaginæ. The structural result was perfect and the patient felt perfectly well. There was no operation for this condition which gave such uniformly good results. In this case the end justified the means.

Dr. Herman J. Boldt said that when the indications were so absolute as in the case reported by Dr. Knipe no criticism should be made, for it was the only operation in which a positive cure of the condition could be guaranteed.

A Review of Seventy-three Cases of Dudley's Operation for Dysmenorrhea and Sterility.—Dr. Samuel M. Brickner reviewed the history of this operation and described it in the words of the author. This operation had been performed at Mount Sinai Hospital 108 times in the past six years, but with certain modifications, as follows: (1) The omission of the denudation of the anterior wall, which they had not considered essential to the proper development of the operation, and which Dudley also now dispensed with; (2) the occasional but infrequent omission of the excision of the wedge-shaped piece of the posterior lip of the cervix; (3) the wide dilatation of the cervix, which rendered the operation easier; (4) using chromicized catgut to close the cervical wound. In all of the cases the operation had been preceded by a thorough and prolonged dilatation of the cervical canal and a light curettage. One of the direct results of this operation was that the position of the os externum in the vagina was changed, and instead of lying against the anterior vaginal wall, if the uterus was in sharp anteflexion, or midway between the anterior and posterior vaginal walls, if the uterus was moderately anteflexed, it now pointed toward the posterior wall and the reception of the semen into the uterus was very much fostered. The direction of the entire lower portion of the uterus was changed. In every case operated upon a careful selection of the cases was made; an examination of the husband was made to preclude the possibility of his being responsible for the sterility. No patient was subjected to the operation who had ever had an inflammatory pelvic disease, or in whom there was any gross pathological condition of the pelvis, or in whom there was diabetes, nephritis, tuberculosis, or grave cardiac disease. In general, the patients presented themselvs with a history of mere sterility dating from eight months to twelve years The other general class complained only of dysmenorrhea. The usual finding was a small anteflexed uterus with a long conical cervix. The external os could not be passed by a sound in many instances, and this constituted in the absence of contraindications an indication for the Dudley operation. Dr. Brickner had made inquiries from the 108 patients operated upon and had received answers from 73. The replies received from the ward patients showed that of 20 who had applied for relief of dysmenorrhea 16, or 55.1 per cent., had been relieved, while 12, or 41.3 per cent., were not relieved, and 1 was made worse. Of 29 who applied for relief of sterility 5, or 17.2 per cent., had been relieved, while 24, or 83.8 per cent., had not been relieved. Delivery had been instrumental in 20 per cent. of the relieved cases and 1 had aborted. Among the private patients 13 applied for relief from dysmenorrhea and 19 for both sterility and dysmenorrhea. Of those who applied for relief of dys-

menorrhea 11, or 84.5 per cent., were relieved and 2, or 15.4 per cent., were not relieved. Of the 19 who applied for the relief of both sterility and dysmenorrhea 42.1 per cent. were relieved of their sterility and 11, or 57.9 per cent., were not relieved of their sterility. Of those who became pregnant, 15.8 per cent. were delivered by instrumental methods. Combining the statistics for the 73 patients they had as a result the following: Of those who applied for relief from dysmenorrhea, 64.3 per cent. were relieved and 33.3 per cent. were not relieved, and 1 was made worse. For those applying for relief from sterility, 27 per cent. were relieved, while 73 per cent. were not relieved. Of the deliveries 8 per cent. were instrumental. Summary: (1) Dudley's operation of posterior sagittal incision of the cervix, with or without the excision of a bilateral wedge, for the relief of dysmenorrhea and sterility was a procedure to be recommended. (2) It was of greater service in the relief of dysmenorrhea than of sterility, although in the latter class of cases the effect was sometimes magical. (3) The resulting scar in the cervix offered no hindrance to labor, dilatation being as normal as possible. (4) Pathological anteflexion, or retroflexion of a hypoplastic uterus, with stenosis of the external or internal os, or of both, was a frequent cause of sterility and of dysmenorrhea. (5) These conditions could be relieved in about 50 per cent. of properly selected cases by Dudley's operation, but no operation for sterility should be performed until the husband was found to possess living spermatozoa, and no operation should be performed for dysmenorrhea without a thorough study of all the features of the case.

Dr. Robert T. Frank said that he had seen a large number of the cases Dr. Brickner had referred to and he could substantiate the statements made as to the value of this operation in selected cases of dysmenorrhea. Dysmenorrhea was relieved in a very large percentage of the cases, but the relief of sterility seemed to him to be rather doubtful. Though the statistics presented showed that only about 25 per cent. of the women were relieved, this was not to be placed to the discredit of the operation. The probability was that most women suffering from sterility had some condition not depending upon a mechanical form of obstruction. In his opinion mechanical obstruction played but a small rôle unless the obstruction was situated in the tube. Most of the other mechanical factors upon which attention was focused at the present day would sooner or later be recognized as negligible. All of them had met isolated cases of sterility supposed to be due to some mechanical factor; later these women became pregnant without operation. For instance, Dr. Frank recently saw a patient whom as a young girl he had treated for extreme dysmenorrhea by palliative measures. She was now married nine months. On account of vaginismus normal relations were impossible. Nevertheless, she was now four months pregnant. Here there was not only the supposed obstructive factor which caused her dysmenorrhea to be reckoned with, but also an additional hindrance, as the spermatozoa had to penetrate the introitus and ascend through the vagina and cervix before entering the uterus. He recalled another striking instance, that of a woman who had been sterile for seven years and who had been advised to submit to a Dudley operation. The patient refused immediate consent, and now, three months later, she had become pregnant. Again they were all familiar with cases of stenosis of the vagina; nevertheless, many of these women became pregnant. In one such case, which Dr. Brickner doubtless remembered, the upper part of the vagina had been reduced to a long, tortuous sinus barely admitting the finest probe. This patient promptly conceived. Coitus through the urethra, in cases of vesicovaginal fistulæ with obliteration of the introitus, were on record with resulting pregnancy. Here the spermatozoa had made their way through an infected bladder and false passage. It seemed to Dr. Frank that there were other causative factors that were more important and usually neglected. The chief factor, in his opinion, would eventually prove to be connected with ovulation. Probably there was a lack of coincidence between ovulation and the time during which the uterus was prepared to receive the ovum. As in animals, when certain pathological conditions were present rupture of the follicles might be delayed, until such a time that the uterus was no longer able to form a decidua for its reception. Dr. Reynolds had mentioned the fact that he could relieve, and had relieved, a number of women by operation in whom he found microcystic ovaries; after perforating these cysts the patients had been relieved of their sterility. It was not the fault of the Dudley operation that success in relieving sterility did not follow, but it was rather, in his opinion, the fault existing in some physical or pathological process, as yet undetermined, which caused a lack of synchronism between ovulation and the optimum time for the reception of the ovum in the uterus.

Dr. John O. Polak said he knew of no conditions more trying to the practitioner than those of dysmenorrhea and sterility associated with anteflexion of the uterus, and he knew of no operation that had given these patients such relief as the Dudley operation or some of its modifications. He found after listening to Dr. Brickner's paper and looking at the diagrams with which the Dudley operation was illustrated that during the last few years he had been doing a modification of that operation. In the first place the operation they did was more extensive; they slit up the posterior lip of the cervix, using a Wylie or a Palmer dilator introduced into the uterus as a guide. In this way they made a clean incision through the posterior lip and internal os that was in perfect alignment. They then removed an extensive wedge out of each side of the posterior lip, placing their sutures in a manner similar to that described by Dr. Brickner, which placed the external os well back at the posterior cervicovaginal junction. They were able to follow many of these women through pregnancy, and they had never seen any extensive cervical tears nor any trouble following labor after this modification of the Dudley operation was done. The character of the labor was not influenced by the operation, and the internal os would dilate far more readily than in other cases. He attributed this fact largely to this: that after the Dudley operation, or some modification of it, the endocervicitis was cured so that cervical hyperplasia no longer continued. When the Dudley operation was properly done and cervical drainage instituted the endocervicitis got well; this, together with the fact that the cervix was placed in the seminal pool, accounted for the sterility cures. A point already mentioned Dr. Polak had noted many times: he found that women with marked dysmenorrhea complained of ovarian pain; the ovaries would be found to be sensitive and enlarged. He had opened the abdomen in such cases and found ovaries with thickened tunica. The earlier a Dudley operation was done the better effect it would have upon the circulatory conditions in the pelvis and better drainage would result. Tender ovaries, beginning to border on the pathological, might be relieved by establishing better pelvic circulatory and uterine drainage. Dr. Polak said that he had also done excision and incision of cysts; this too he found had a decided influence on pregnancy by allowing a better ovarian function. It was now his custom to combine with the Dudley operation Reynold's procedure, separating the cellular tissues from the front of the uterus through a transverse incision at the uterovaginal junction anteriorly.

Dr. Dickinson was glad that so much stress had been laid upon the proper selection of cases for doing the

Dudley operation. The operation had a very limited field, and they were often disappointed in their results. In some patients the uterine canal might be stretched, or stems inserted, or some other simple means might be employed without having recourse to operation. The most successful cases in this line of work were the worst cases. He had used the stem for years for the relief of sterility and it was only within recent years that he had resorted to the Dudley operation.

Dr. Simon Marx said that he had done a few of the Dudley operations and he had seen similar results from other means. He thought that he could give 25 per cent. successful results, and even a greater percentage so far as dysmenorrhea was concerned, by the ordinary methods. In those cases of fairly marked diversions of the uterine canal he had seen them disappear after operation. In most of the cases that he had seen he had used the modified Wylie glass intrauterine stem instrument, which produced perfect drainage; this was used for months. Dr. Marx believed that the cause of dysmenorrhea and the cause of sterility was a mechanical one. In the first place there was a flexion of the uterus, especially marked at the internal os; the most successful results followed the stretching of the internal os as far as they could. The sphincter muscles should be paralyzed. He used a glass stem which had been thoroughly sterilized, and he got practically the same results. He admitted, however, in some of the cases in which the glass stem was used he met with high temperatures, in one case a temperature of 106° F. This case resulted in a failure.

Dr. Herman J. Boldt said that the most striking features of the paper, in addition to the statistics given, was the careful selection of the cases. Dr. Dudley had demonstrated the operation to him shortly after he devised it, and Dr. Boldt had been doing it since. If the cases were carefully selected the operation of Dudley in the class of cases with a marked anteflexion, dysmenorrhea, and sterility, dependent upon mechanical obstruction of the cervical canal, would be a good operation. Pozzi's operation likewise was an excellent one.

Dr. W. Gill Wylie said that this operation had been done years ago by Dr. Sims and he had seen some of the cases; as a rule the results were good. Any one, however, who divided the internal os seriously harmed the patient unless the internal os was thoroughly dilated and remained dilated for some time. The canal should be thoroughly divulsed and a drainage tube should be introduced which should be left in place for months. If this line of work was carried out skilfully he thought that one could guarantee a cure in nine out of ten cases of dysmenorrhea if there were no serious complications outside.

Dr. C. C. Sichel said that most of these cases of dysmenorrhea and sterility were either due to some mechanical obstruction or other causes; dilating operations usually resulted in a cure of these cases with mechanical obstructions. Dudley's operation did not absolutely cure the condition nor did it straighten the canal in all cases. The dilatation and curettage employed by him probably caused the cure and should be given the credit for the good result which followed the operation. In the limited number of instances in which he had performed the Dudley operation he felt that as the dilatation and stretching of the sphincter in operation for hemorrhoids was the point of paramount importance so, in Dudley's operation, dilatation and curettage of the cervix was a point of equal importance.

Dr. Samuel M. Brickner said there were many roads which led to Rome. He held no brief for this operation or other operations for the cure of dysmenorrhea. He believed, however, in reporting progress. He was a firm believer in this operation and he was at the same time aware that there were other methods which reached the same result. If he praised the Dudley operation he did so because in his experience it was fruitful and beneficial. In answer to Dr. Frank Dr. Brickner quoted the words of the Pharisee: "I know not, whereas I was blind, I now see." After the operation many of the women became pregnant within four or five weeks. This made him a firm believer in this operation; cause and effect, as in all biological relations, showed that there was some definite relation one with the other. In answer to Dr. Wylie, Dr. Brickner said that Dr. Sims never performed this operation, although no doubt his teachings had been influential in spreading bloody operations upon the cervix for dysmenorrhea and sterility.

Radiography of the Distended (Collargol, Argyrol, Oxygen) Renal Pelvis and Ureter.—Dr. Leopold Jaches and Dr. H. D. Furniss presented this communication and gave a lantern slide demonstration. It was not an uncommon occurrence that the routine *x*-ray examination of the urinary tract failed to satisfy either the röntgenologist or his colleague who referred the patient to him. Symptoms of obstruction, probably due to calculus, might be present, but no calculus could be seen. Means of determining the cause and location of the obstruction resulted in the introduction of the *x*-ray catheter, but this did not solve the problem. What was wanted was to make possible the reproduction on the *x*-ray plate of the renal pelvis and the lumen of the ureter and such constrictions as might be present. In 1906 Foelcker and v. Lichtenberg published a report with very satisfactory results, in which they used a 5 per cent. solution of collargol. Since then argyrol has been substituted by other investigators with equally good results. The information to be obtained by the technique they followed might be summarized as follows: (1) The extent and shape of the renal pelvis and its relation to the skeleton. (2) The angle at which the ureter entered the pelvis. (3) Constrictions of the ureter. (4) Kinks due to displacement of the kidney. (5) Renal tuberculosis and tumors.

Dr D. H. Furniss exhibited a number of radiographs made by Dr. Jaches and himself showing the kidneys and urters after injection with oxygen, argyrol, and collargol. Some of the radiographs showed mild and marked hydronephrosis, strictures of the upper and lower ends of the ureters, displacements of the kidneys, and in one the marked distortion of the renal pelvis due to a large hypernephroma. Dr. Furniss thought these good pictures were due to team work between himself and Dr. Jaches and believed that such team work was essential to good results. They had obtained the best results with 40 or 50 per cent. argyrol in a 2 per cent. boracic acid solution and injected with a piston syringe. They used a small ureteral catheter to allow the easy return of the solution along the catheter and thus prevented over-distension of the renal pelvis. The injection was started a minute before the exposure was begun and continued during the exposure. The only cases in which there was pain were those in which there was some form of ureteral obstruction, and in these the pain had been of the type for which the examination was made. In two cases of dilatation of the entire ureter, in each of which a number of examinations were made on different days, there was absolutely no sensation in the renal region. This seemed to be evidence that any pain that might be experienced was mechanical rather than due to the irritating effects of the injected solutions. After the radiograph was made the pelvis of the kidney was irrigated with boric acid solution, the return being alongside the catheter. Where there was marked dilatation of the whole ureter it was essential that the bladder be well filled if a picture of the ureter was to be had; otherwise the return flow was so rapid that the proper distension was not produced. Dr. Furniss said that from their experience they believed that in cases with symptoms referable

to the urinary tract in which other methods of diagnosis had failed to reveal the cause, such an examination was essential, and a negative opinion was not possible until such an examination had been made.

Dr. Eugene Wilson Caldwell said he could see no excuse for using air or oxygen in this work because of the confusion which might arise; it would be very hard to distinguish between gas contained in the renal pelvis and that contained in an overlying intestine. Between the use of collargol and argyrol there seemed to be but little choice. At the Mayo clinic at Rochester, Minn., over 650 patients had been examined; there they used a 10 per cent. solution of argyrol. Dr. Caldwell thought that the solutions should be weaker. The success of these examinations depended upon the success in the use of the cystoscope. Better work could be done with the employment of a better technique.

Dr. Wm. H. Stewart called attention to the advances that had been made in this line of work; in many cases of persistent renal colic the diagnosis could be cleared up which with the ordinary radiographic examination gave negative results. In these cases the indications were to examine the renal pelvis and ureters by means of the collargol injection, looking particularly for kinks or obstructions. Some surgeons had a certain amount of reticence about these injections and one surgeon did not wish him to use the collargol injection because he feared painful or disastrous results might follow. Dr. Stewart's procedure was to make a preliminary radiographic examination; this tended to educate the patient as to what was coming from the apparatus so that on further examinations perfect immobility could be secured. If this examination showed a suspicious shadow in the line of the ureter the question at once arose whether it was within or without the ureter. This was especially so in the pelvic region where so frequently shadows of the so-called phleboliths were seen. Given this condition he preferred to have an opaque or *x*-ray ureteral catheter passed for a radiographic examination *in situ* rather than the use of a stiletted catheter. If, however, the preliminary examination was negative and the symptoms persisted, the indications were to inject collargol into the pelvis of the kidney and ureter with the possibility of finding an obstruction. Even with this method one might get negative results; there were a number of instances recorded in which a kink was seen when the patient was in the upright position, but not seen in the recumbent position. This had been demonstrated by Dr. Stover of Denver, Col., a number of times. If the examination was to be of the renal pelvis, collargol was used immediately. He never set the compression diaphragm upon the patient before the injection of collargol, as it was possible to produce pressure enough to interfere with the free injection and produce an artificial obstruction. The cystoscopist commenced the injection; when the patient complained of distension the diaphragm was set and the exposure made, gentle distension being kept up by his team mate. Some improvement should be made in the cystoscope so that it could be removed after the catheter had been passed without the danger of pulling the catheter with it. He had seen expert cystoscopists neglect to lower the director or the cystoscope which gave them the impression of having met with an obstruction in the passage of the catheter; in one case this caused great confusion, as it was demonstrated afterward that the shadow was outside the ureter.

Dr. Edward L. Keyes, Jr., said he felt very uncertain regarding the interpretation of many of the pictures made, and it was very difficult to get patients to submit to the number of examinations required. The functional test of the kidney was after all much more important for the preliminary diagnosis in patients with pus in the urine than the argyrol injection test. The *x*-ray and functional tests were requisites. If there was pus in the kidney as a rule the argyrol injection did not tell anything of importance. Injection radiograms were only useful in the diagnosis of obscure renal pain.

Dr. Leo Buerger said that this useful method was very much neglected in the city of New York. In doing this work a prerequisite was a proper knowledge of the cystoscope and how to introduce the catheters quickly; one must master the technique.

Dr. Edwin Beer said that, judging from the remarks of the previous speakers, they seemed to lay very little stress on the dangers incidental to pyelography. There were distinct risks with this procedure and he wished to emphasize that pyelography was not an innocent procedure. He believed that much more work would have been done along these lines had not the danger of severe collapse been experienced by most experimenters. He had seen three such cases; with such experiences fresh in one's mind one naturally advised restricting pyelographic work to those cases in which it was strictly indicated. In addition to collapse, necrosis of the kidney had recently been reported after the use of this technique. The class of cases in which pyelography might serve a useful function were as follows: (1) Cases of suspected ureteral calculus where all other means had failed to make the diagnosis. In these cases the ureterograph would be capable of demonstrating a dilated ureter above a point of constriction the site of the calculus. (2) In strictures of the ureter, ureterographs would be as useful as under (1). (3) In demonstrating dilated pelves, *e.g.* hydronephroses due to mobile kidneys. In these cases, if the pelvic enlargement could be shown by injecting colored fluid through the ureteral catheter, and thus measuring its capacity, it was by far preferable to pyelography because less risk attended the work. He doubted very much the usefulness of pyelography to show the clinician the presence of a neoplasm which might distort the contour of the pelvis. No doubt such distortions occurred, and were significant as had been demonstrated, but whether necessary to the clinical picture, or essential to diagnosis, the future would have to show more definitely. With regard to the interpretations of ureterographs and pyelographs, if the pictures were very definite and the contrasts between dilated and stenosed parts very great, he believed that one was justified in drawing inferences. If not, one should be wary of spasmodic ureteral conditions which might simulate stenosis, and not rush in rashly and diagnose actual pathological stenoses. Dr. Beer concluded his discussion by stating that while the field for the work might be fruitful in carefully selected cases, indiscriminate work at this stage was harmful and he advised going slowly.

SECTION ON PEDIATRICS.

Stated Meeting, Held November 9, 1911.

Dr. William Shannon in the Chair.

This was a joint meeting with the Philadelphia Pediatric Society and the New England Pediatric Society.

Acute Duodenal Indigestion in Children.—Dr. Fritz B. Talbot of Boston read this paper. He said that the intestinal canal was sterile at birth, but soon became infected and remained so for the rest of life. The bacteria tended to belong to the acid-forming group when the infant was fed with human milk, and to the putrefactive or alkali-forming group when the food was cow's milk. Putrefaction commenced when the baby began to take cow's milk, which contained larger quantities of casein than human milk, and thus gave the putrefactive group of bacteria a suitable food upon which to grow. Bile had the property of activating the pancreatic proferment steapsinogen into steapsin. Fat emulsification was favored

by the presence of bile; when bile was occluded from the intestinal canal the absorption of fat was interfered with and metabolism was abnormal. Bile had no influence upon the digestion of sugar, but it had been known for a long time that sugars had an unfavorable influence upon patients with acute duodenal indigestion. This disease was a relatively common one; during the past year there had been 24 cases in the Children's Medical Out-Patient Department of the Massachusetts General Hospital. The onset of the disease might be sudden, with fever, vomiting, pain in the stomach, jaundice, clay-colored stools, bile in the urine, loss of appetite, etc.; or it might be insidious, without fever, following some indiscretion in diet, more especially as regards the intake of fats and sugars. The disease appeared as a complication of such infections as otitis media, diphtheria, and the exanthemata in 15 per cent. of the cases. The onset was sudden with fever and vomiting in 75 per cent.; the liver was enlarged in 74 per cent., and tender in 13 per cent.; the spleen was not felt in any case. Urobilinogen was absent from the urine in every case where there was complete obstruction to bile and was found in excessive amounts when the obstruction was removed. The stools were recorded as white in 36 per cent., creamy in 14 per cent., and clay-colored in 50 per cent. of the cases during obstruction. When there was complete obstruction of the common duct bile in the form of bilirubin was dammed back into the circulation, colored the tissues, and a part overflowed in the urine. The fat in the food was digested and absorbed only in part, and as a result there was a clay colored acholic stool which was composed almost entirely of fat. In the majority of the cases these fats were in the form of soaps. In some cases there was constipation, in others diarrhea; the latter was due to the prolonged irritation of the intestinal mucous membrane, due to the stagnation and decomposition of fat which was brought about by the action of the intestinal juices and bacteria, thus complicating the duodenal indigestion with a secondary intestinal indigestion. When the bile again flowed into the intestine the fat quickly disappeared and normal quantities of uribilinogen appeared in the urine. With regard to the treatment it was obvious that fats and sugars should be excluded from the diet. Proteins, especially meat, fat-free milk, or skimmed milk, and thoroughly cooked simple starches might be given with safety. Tincture of nux vomica should be given to stimulate the appetite. Any mucus plug in the bile duct might best be reached by large doses of an alkali, as, for instance, bicarbonate of soda.

Dr. Alfred Fabian Hess said that about one year ago he devised a duodenal tube which was a modification of the Gross tube used in adults. With this he found he could readily reach the duodenum, draw up the juices and make a study of the ferments. Although this tube worked fairly well he felt that it could be improved upon and, some months ago, he found that with a rubber Nelaton catheter he was enabled to pass through the stomach and enter the duodenum and more readily and quickly obtain the duodenal juices. This permitted him to make a study of the secretions, as well as of the functions of the pylorus and certain pathological conditions, such as spasm and stenosis of the pylorus. In acute catarrhal jaundice they met with one form of duodenal indigestion; the bile was dammed back, there was a lack of fat digestion, and fat appeared in the stools. This was a small part of duodenal digestion, for the duodenum into which various ferments were poured was the main seat of digestion. When anything interfered with these ferments duodenal indigestion might result. There could be motor as well as secretory indigestion. Sometimes the food passed through the duodenum more quickly than at other times. Where there was an interference with bile secretion jaundice did not necessarily result. The subject Dr. Talbot had brought before them was one that would develop greatly in the future and would be approached not by an examination of the urine and of the ferments in the stools, but by a study of the ferments themselves in the duodenum; this duodenal catheter enabled one to approach this study. They should know more about duodenal digestion.

Dr. Herman Schwarz emphasized the importance of knowing what was happening in various parts of the intestinal tract. Much knowledge had been gained in their work with animals, and Pawlow and his assistants had helped them. It was a step in the right direction to understand just what duodenal and other kinds of digestion were. Catarrhal jaundice and the effect on digestion of the absence of bile, especially on the digestion of fats, should be studied more and especially in that type of cases which occurred not so infrequently, congenital stenosis of the bile ducts. In this condition there was practically no digestion of fats and it was remarkable to find that, instead of 4 or 8 per cent. of fat, 60 or 70 per cent. of the fat would be found in the stools. It was almost impossible to dry stools with such a high percentage of fat. Under normal conditions it was surprising the amount of fat the small intestinal would take up.

Dr. Henry Dwight Chapin said that one year ago he had made a study of the motility of the stomach, especially in atrophic infants. The trouble in these cases was not so much with the secretions as it was with the deficient muscular action. Duodenal feeding in this class of patients was very promising.

Dr. John Lovett Morse of Boston said that duodenal indigestion occurring in young children was much more common than generally supposed. He had seen a number of instances occurring in the beginning of the first week in life. One should be on the lookout for this trouble at any age. He said he was particularly interested in Dr. Talbot's statement that these patients did not do well when given sugars, but that they did do well when given starches.

A Study of Streptococcus Antibodies in Scarlet Fever, with Special Reference to Complement Fixation Reactions.—Dr. John Albert Kolmer of Philadelphia said that the latest contribution to the bacteriology of scarlet fever had been made by Vipond. In his own investigations of the glands in 26 cases of scarlet fever he had failed to find any organism resembling those described by Vipond. The object of their studies had been twofold: 1st. To determine more accurately, if possible, by such a study the relations of streptococci to scarlet fever than was possible by morphological and biological studies alone. 2nd. To determine if the method of streptococcus immunization as practiced in Russia could be supported by laboratory investigation. The same cultures and immune sera were used in these experiments. These experiments led them to believe that a streptococcus produced a specific antibody up to a certain limit. The specific nature of these antibodies was seen by complement fixation reactions in high dilutions between a streptococcus immune serum and its antigen. With low dilutions the specific nature of the antibody was not brought out. Scarlet fever streptococci tended to produce their own specific immune serum, but streptococci causing septicemia and non-scarlatinal angina also produced their own immune sera. The fact that they found but 11.2 per cent. positive reactions in scarlet fever tended to show that streptococcus infection in scarlet fever severe enough to produce immune bodies was not so common as generally believed. One of three toxic or malignant cases yielded a positive reaction. Since it had been proven almost to a certainty that streptococcus was not

the cause of scarlet fever it was difficult to understand how immunization with streptococcus could prevent scarlet fever. They could understand, however, that such immunization might be of value in preventing or mitigating secondary streptococcic infections which were present in at least 11 per cent. of scarlet fever patients and responsible for severe primary lesions and complication. Likewise it was possible that such protection would result by an increase in opsonins against streptococci. In their study they had endeavored to ascertain if the streptococco-opsonic index could be raised by an injection of heat killed streptococci, and also to find out whether the opsonins produced by the different strains of streptococci were specific in nature. Their study had led them to conclude: 1. That it was possible to raise the streptococco-opsonic index by the injections of organisms killed by an exposure of 60° C. for one hour. This increase, however, was very slight with three or less injections and became apparent only after a relatively large number. 2. That the increase in the quantity of opsonin after three injections was so slight as to make the likelihood of establishing immunity against streptococcic infection very dubious. 3. That the opsonins were more or less specific toward the strains used in the process of immunization. They had also worked on the problem as to whether streptococci stimulated the production of agglutinins upon which investigators were far from agreeing. They had found that streptococcus agglutinins were produced slowly by experimental immunization and the quantity was quite variable; that these agglutinins were apparently non-specific in character and of no value in differentiating streptococci; that they were demonstrated in 12.5 per cent. of scarlet fever patients, but only in comparatively low dilution of serum; that there was no relation between agglutination and complement fixation antibodies or between agglutinins and opsonins. They agreed with those who claimed that streptococci found in scarlet fever patients, whether in the throat, suppurative lesions, or in the blood, could not be differentiated from the streptococci found normally in the throat or in septic conditions by morphological or cultural characteristics. If they were to claim a specific streptococcus for scarlet fever, a similar claim might be made for every other streptococcus infection; thus to claim a specific streptococcus for endocarditis and another for puerperal sepsis seemed to be out of the question. One fact was certain, namely, that all severe, septic and fatal cases of scarlet fever were not due to the streptococci. They were of the opinion that the streptococcus found in scarlet fever belonged to the general class of streptococci and was modified in some way during the course of the infection so as to give it a somewhat specific antibody and occasionally temporary cultural characteristics. This was also true of the streptococci causing septicemia and simple sore throat. With regard to streptococcus immunization, while the reports of the Russian physicians were on the whole convincing, the disease was so protean in character, was frequently disseminated in such an inexplicable and confusing manner, and they really understood so little concerning the infection that they should view these enthusiastic reports with healthy skepticism.

Dr. Richard M. Smith of Boston said that it had never been definitely settled that the streptococcus had any direct etiological connection with scarlet fever. Despite the large amount of work which had been done on the single point of specificity of the streptococcus found in scarlet fever, it was far from proven that the same type of streptococcus was always found in every case of scarlet fever or that the streptococcus found in scarlet fever was in reality different from that found in other diseases. Until this point was definitely proven they must remain skeptical in assigning the streptococcus as the cause of scarlet fever. The fact that streptococci were found in scarlet fever patients and that the blood of scarlet fever patients was changed in its reaction toward streptococci did not prove the streptococcus as the etiological factor of the disease. Scarlet fever lowered the resistance of the individual to any intercurrent infection. Tunnicliff had shown that the opsonic index in scarlet fever patients was not only low for the streptococcus, but also for the pneumococcus and the staphylococcus. Hence it was not at all surprising that this organism should gain a foothold and develop rapidly. The work of the Russian physicians in immunization was most interesting and important, but it must be borne in mind that the natural immunity to scarlet fever was very great. It was not at all uncommon to have a single member of a family contract the disease and none of the others be affected. It was not unusual for one child in a school to have scarlet fever and all the others escape although there was general exposure. It seemed that the number of persons actually protected by the vaccines in a Russian community must remain a matter of speculation. For a convincing demonstration of the value of vaccines the number of inoculated cases must be large, the control individuals many, and the observations extended over a long period of time. He had had but one opportunity to try this vaccination. An epidemic of scarlet fever occurred in a Boston institution last winter, but despite the fact that all of the children were vaccinated many of them three times, no influence was evident on the spread of the disease. The children contracting the disease had light cases, but he could not say whether or not the vaccination was responsible for this. Thus far it had not been proven that streptococcus vaccine could prevent scarlet fever. The value of vaccines, and perhaps serum, in influencing the complications of scarlet fever was quite another matter. The majority of the patients who died succumbed to the toxemia of a secondary infection due in the majority of cases to the streptococci. If by giving vaccines or serum early in the course of the disease they could prevent secondary infections they might moderate the severity of the disease and greatly reduce the mortality. If those already infected with the streptococcus were vaccinated their powers of resistance might be increased so that they could overcome the infection and thus the mortality would be lowered. It was in this direction that they were to hope for most benefit from vaccines and serum.

Dr. William C. Thro said that only those actually engaged in this work could understand how tedious and laborious it was. As strain after strain was added to the antigen, more and more positive results were obtained. An increase to eleven strains would give more positive results than when only two or three strains were used.

Dr. Homer Swift said that the work recently done demonstrated that the streptococci were not the etiological factors in scarlet fever. The work done with the experimental fever in animals which was similar to scarlet fever in man seemed to indicate that scarlet fever was caused by a filterable virus. During the past year they had produced a scarlet fever-like disease in monkeys after first having depressed their resistance by injections of saline solution. A German investigator injected monkeys with the coating of tongues from patients whose lymph nodes were free from streptococcus; they had used lymph nodes and, after an incubation period, fever-coated tongue, the typical strawberry tongue, and eruption followed by desquamation similar to that of scarlet fever occurred. He had also passed the extract of the glands through filters and obtained scarlet fever-like disease in monkeys. He had not obtained similar disease from the injection of streptococci.

Dr. Matthias Nicoll, jr., said that while the streptococcus as a causative factor in scarlet fever seemed to be losing ground, they had not yet discovered the true nature of the infectious principle in scarlet fever and unless the finding of this infectious agent should lead to the means of preventing the disease the streptococcus would still have to be largely reckoned with. It was the cause of death in the vast majority of the cases. After a considerable experience in the employment of the antistreptococcus serum, both by the subcutaneous and intravenous methods, he was unable to advocate its use in scarlet fever except in those cases which might be classed as general septicemia. On the other hand he was thoroughly convinced of its great value when applied freely and at short intervals to the mucous membrane of the pharynx and tonsils. He had demonstrated that in 18 cases of scarlet fever, ill from two to twenty-four days, enlarged but not suppurating lymph nodes, in four instances in the cervical region and in nineteen in the inguinal, together with an inguinal node removed postmortem from a septic case of the disease, in no instance showed the presence of streptococci or of other organisms. Here was a disease which involved the lymphatic system from the neck to the groin in forty-eight hours or less and apparently without the aid of any pyogenic organism. They might be justly suspicious of all reported cases of scarlet fever occurring in rabbits, such as Cantacuzene had recently announced. The rash of scarlet fever was frequently difficult of dagnosis in human beings and in an unshaved rabbit it was largely a matter of personal opinion. Furthermore, shaving rabbits did not better the situation, as this process, owing to the delicacy of their skin, produced a dermatitis which persisted for a number of days. The temperature curve in these animals was erratic and easily disturbed, and their throats and tongues were eminently unsuited to clinical observation.

Vaccine Inoculation, Prophylactic and Curative, of Typhoid Fever.—Dr. J. M. Phalen of the United States Army and Dr. J. G. Callison presented this paper. In speaking of the vaccine in this paper they had reference only to that used in the United States Army, which was prepared by Major Frederick F. Russell in the laboratory of the Surgeon General's Office in Washington. An old culture which had ceased to be pathogenic and which produced an abundant growth upon agar was inoculated upon agar in flasks constructed so as to give a known surface of media. At the end of eighteen hours the agar cultures were washed off with normal salt solution, put into flasks, and the culture killed by subjecting it to 55° or 56° C. over a water bath for one hour. During the process of sterilization, a count was made of the bacterial suspension for the purpose of standardizing, after which the culture was diluted with normal salt solution so that one c.c. contained one billion bacilli, and then one-quarter of one per cent. tricresol was added. It was then tested for both aerobic and anaerobic bacteria, and as a further measure of safety guinea pigs were inoculated with it. It was sealed in ampoules containing from one to twenty-five c.c. Every man enlisting in the Army was given the immunizing dose. The first injection was administered at the time of enlistment and consisted of one-half of a c.c. The second and third injections were given at intervals of ten days and consisted of one c.c. each. The inoculation was made into the deltoid muscles near its insertion by means of an ordinary hypodermic syringe. They painted the skin over the site of the inoculation with tincture of iodine and after the inoculation touched the needle wound with the same solution. The reaction following the inoculation showed itself locally by an area of hyperemia around the wound, and more deeply by a circumscribed area of induration; constitutionally there was some fever and malaise, and in the more severe cases there might be gastrointestinal and nervous disturbances. It was to the records of our Army, together with those of England and Germany, that they must look for evidences of the practical value of vaccination against typhoid fever. The latest figures available from the service of the British Army were those of Col. R. H. Firth, R.A.M.C., covering the Colonial Army in India during the period from 1906 to 1910, inclusive. In 1906, among a military population 66 per thousand of whom had been innoculated, the typhoid rate was 15.6, the death rate 3 19; in 1907, the inoculated population having been 143 per thousand, the typhoid rate was 13.1, and the death rate 2.77; in 1908, the inoculated population having been increased to 225 per thousand, the typhoid rate was 14.5, and the death rate 2.76; in 1909, when the inoculated population was 613 per thousand, the typhoid rate was 8.9, and the death rate 1.58; in 1910, the protected population being 823 per thousand, the typhoid rate was 4.6, and the death rate 0.63 per thousand. In 1910, in a strength of about 70,000 men, 306 cases of typhoid occurred; in about 60,000 inoculated men there were only 155 cases. At the same time there occurred 151 cases among 10.000 men who were not inoculated. In the German Army in Southwest Africa during the Hereros campaign, from 1904 to 1907, there were 16,496 men who participated, 287 of whom took the inoculations. Among this force there were 1277 cases of typhoid fever, the rates being 5.09 per cent. for those inoculated and 9.84 for the uninoculated. The death rates were still more striking; among the inoculated the rate was 6.47 per cent., while for the uninoculated it was 12.8 per cent. Nowhere did they get such convincing evidence in favor of the practice of typhoid immunization as from the records of our own Army. During the past three years 60,000 men had completed the three inoculations, but twelve cases of typhoid fever had developed during this time and no death had occurred. The record of the camp at San Antonio, Texas, during the past summer was most instructive. The division of 12,800 men stationed here had all been inoculated and but one case of typhoid fever developed; that was in a Hospital Corps man who had not completed the three injections necessary for protection against the disease. During the same time there were 49 cases of typhoid fever, with 19 deaths, in the city of San Antonio. During the same period between three and four thousand men were in camp at Galveston, Texas, and no case of typhoid occurred among them, while the city of Galveston furnished 192 cases of the disease during the existence of the camp. The city and the camp had the same water, milk, and food supply. About three thousand men were scattered along the Mexican border, in small camps, many of them in localities where typhoid fever was present, yet only one man contracted the disease, and he recovered. It was inconceivable that with such conditions the practical abolition of typhoid fever could have been effected without the use of the immunizing inoculations. In regard to the paratyphoids it seemed that neither the degree nor the constancy of the group reactions would warrant them in believing that typhoid inoculations would be protective against the paratyphoid bacilli. In the Tropics it was likely that a fair proportion of the continued fevers were paratyphoids, and in such localities, inoculation might prove comparatively disappointing. Where the proportion of paratyphoid infections was found to be high the use of a mixed typhoid and paratyphoid vaccine might be indicated. The duration of the immunity conferred by inoculations was an important matter not yet decided. Firth placed the period at thirty months after the first immunization. Leishman thought that reinoculation should be given after two years. This was a point

still to be cleared up as was also the question as to whether, like smallpox, a second injection would confer practically permanent immunity. The sum of the opinion of men who had treated typhoid fever by means of the vaccines was favorable. They agreed that it shortened the period of fever and the total duration of the disease; that it reduced complications and relapses; and that the mortality was lessened, being in the cases thus far reported 4.9 per cent. In the cases reported by Meakin and Foster of Montreal a distinct crisis was noted following the second inoculation in 50 per cent. of their cases. These men gave the largest doses of vaccine, from one to two billion bacilli. It had apparently been directly life-saving in a few all but hopeless cases. All were agreed that in cases where it caused no improvement it had done no harm. The dosage employed in the earlier cases usually ran from ten to one hundred million, but with increasing confidence the dosage had been increasing until at present it was usually from one hundred to five hundred million. It was probably that those who had been reporting negative or discouraging results had been using too small doses and that with increasing dosage even better reports than had thus far been received would be obtained.

The Therapeutic Use of Vaccines in Typhoid Fever.—Dr. James G. Callison said that he had treated in all 35 cases of typhoid fever with vaccines. Since the last report he had made he had treated 11 cases with one death and no relapses. In the 35 cases there had been four deaths and one relapse, with an unusual absence of complications. The causes of death were femoral phlebitis and its sequelae, double pneumonia, meningococcus septicemia, and a ruptured spleen. Charts of six cases were shown as illustrative of the changes in temperature which were to be interpreted in the light of what was known as to the time of the production of antibodies following the inoculation of the vaccines. The charts showed that there was a marked change in the temperature at a time corresponding to the beginning and rapid production of the opsonins and agglutinins in healthy individuals. The contraindications to the use of the vaccines had not been worked out but it seemed certain that severe clinical manifestations did not forbid its use. In his article in the Medical Record, June 24, 1911, Dr. Callison had collected 323 cases of typhoid fever treated with vaccines which showed a mortality of 5.2 per cent.: certainly this compared favorably with the 16 per cent. reported by Bellevue and the Allied Hospitals. Dr. Callison had been using an initial dosage of five hundred million, repeating the injections at four-day intervals, and increasing the dose one hundred million at each subsequent injection. Any method of treatment that could show so low a percentage of deaths and relapses was worthy of further trial.

The Dietetic and General Management of Typhoid Fever in Children.—Dr. Charles Gilmore Kerley read his paper. He stated that the ill child required food of a definite nutritional value in assimilable form. A variety of food was required and the food selected should be made agreeable to the patient. These points covered both the science and the art of feeding the sick child. There was no ready-made diet in any illness in a child any more than there was one ready-made scheme for artificial feeding of infants with digestive derangements. He found it necessary at the onset of every illness to discontinue milk and solid foods because the child's capacity for food was lessened. He gave a laxative sufficient to produce a few watery evacuations. As a temporary food the child was given flavored gruels and perhaps one of the dried milk foods until the nature of the illness was determined. In typhoid fever the diagnosis was rarely made under a week and by following out this plan, when the diagnosis was made, they had the intestine free from distension with gas and undigested milk, and consequently a lower temperature and less toxemia. With the diagnosis of typhoid fever positive the diet schedule might include gruels, two ounces of cereal to a pint of water. To make these gruels palatable, broth, milk sugar, or sherry wine might be added. He allowed well-cooked rice, farina and cream of wheat, served with butter and cane or malt sugar, or with maple syrup. Milk foods were rarely given oftener than once a day and included matzoon, kumyss, *citeciss milch* of Finkelstein, and skimmed milk. The latter was always given mixed with a gruel. The whites of two, three, or four eggs were given daily with orange juice. Lemonade and weak tea with the addition of cane sugar was given between the regular feedings. Early in the convalescence scraped rare steak, custard, soft boiled eggs and junket were allowed. It was entirely wrong to assume that the diet they began with must be continued throughout the attack. Feedings were never given oftener than at three-hour intervals. Fat in considerable quantities was poorly digested by young typhoid fever patients; it might, however, be given in small quantities mixed with other foods. Proteids should not be given in considerable amount until they know something of the course of the disease. Dr. Kerley thought that the milk diet had been used too much in typhoid because it was easier for the physician, easier for the nurse and the family, easier for everyone but the patient. Mixed feeding had been neglected because physicians failed to realize that other foods might be taken care of more easily than milk and because of the fear that they would be criticised for departing from the established practice. It had been his observation that in the milk-fed cases the disease had been more severe and the illness had lasted longer, emaciation was greater and convalescence, consequently, more protracted. On the milk diet tympanites was the rule, while on a mixed diet it was the exception. Drugs had been of no service in Dr. Kerley's experience with typhoid except to produce an evacuation when there were not two in twenty-four hours and to control the evacuation when there were more than four in twenty-four hours. Most children could be kept comfortable with a temperature of 104° or a little more and under such conditions no attempt should be made to reduce it. If the temperature went higher than this he used the cool pack. The thorax and abdomen were wrapped in a towel at 95° F. and the towel was cooled by sprinkling with colder water. A cold pack applied to the head would usually relieve the restlessness, irritability, and sleeplessness. The advantages claimed for this method of management were a milder course, shorter duration, more prompt convalescence, and usually, absence of complications.

Dr. Charles Fife of Philadelphia said he had not given up entirely the use of milk in feeding children with typhoid fever, although he believed it could be used with damage if carried to a certain extent. One should study with care the digestive power of the patient. Milk was an important food element, and when skimmed it had a place in the treatment of these cases and should be used more than once a day.

Dr. Warren Coleman said that during the past few seasons he had been using a diet the main object of which was to supply the patient with an amount of food necessary to cover the amount of energy lost. During the years 1908, 1909, and 1910 there had been 875 cases and 137 deaths in Bellevue and the Allied Hospitals. During this same period there had been 102 cases on a high caloric diet, with 11 deaths, or 10.8 per cent. If these high caloric diet cases were subtracted from the total there would be left 773 cases with 126 deaths, or 16.3 per cent. One of the interesting points that Dr. Coleman brought out was that on the use of the high caloric diet there was a

subsidence of the diarrhea with which the patients entered the hospital; in those cases in which hemorrhage occurred, the loss of blood was very little; again, the convalescence was much shorter. He believed that high caloric feeding for typhoid fever patients was followed by the best results.

Dr. August Seibert said he had been connected with St. Francis Hospital for twenty-two years and he had not used milk in the treatment of typhoid fever during that period. Diarrhea, intestinal disturbances, toxemia, etc., were all increased when milk was given. The intestinal tract should be thoroughly cleansed every day.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirty-seventh Annual Meeting, Held at Nashville, October 17, 18, and 19, 1911.

The President, Dr. Robert H. Babcock of Chicago, in the Chair.

(Concluded from page 1151.)

The Importance of Early Diagnosis of Chronic Kidney Inflammation.—Dr. D. M. Hall of Memphis stated that the only way to diagnose these cases early was to examine the urine of every patient who had any of the usual beginning symptoms, such as persistent headache, indigestion, asthmatic attacks, etc., which did not yield promptly to treatment. He insisted on repeated examinations both qualitative and quantitative. It was astonishing how often the physician satisfied himself with one qualitative examination and how seldom a quantitative examination was thought of. A great many cases of chronic nephritis might be diagnosed months and perhaps years earlier if a thorough examination were made. He had no new treatment to propose. He believed the weapons ordinarily used, such as dieting, elimination, and resting the kidney, could be wielded with curative results in the early stages of some of these cases. One of the essential things was to remove the cause. In most cases we could not discover a definite cause. In these cases the best we could do was to remove all of those things which might be causes. As a causative factor in the production of chronic nephritis he thought that autointoxication of intestinal origin was not given sufficient prominence by most authors. Therefore, attention to the alimentary canal in these cases was one of the most necessary things. These people should diet themselves rigidly, never overeating or eating anything indigestible, and always keeping the intestinal canal free of indigestible matter by means of frequent purgatives. These purgatives, especially salines, not only cleaned out the bowel, but eliminated the toxic materials as well. Alcohol in all forms must be avoided. People should also be very careful to avoid exposure to cold and damp, and should lead regular lives and take moderate daily exercise. If cases were seen early and this treatment was followed rigidly for years, he thought that a large percentage of cases would live and enjoy health years longer, and some of these would ultimately be cured. The kidney lesion ceasing to be progressive, the healthy portion of the kidney was able to do all the work, and the diseased part simply remained as a scar.

Protracted Intervals Between the Births of Twins.—Dr. W. W. Vinnedge of La Fayette, Ind., reported two cases. In one case there was an interval of seven weeks between the births of the children. After a natural labor of about six hours the first child was born, a male, weighing three pounds. Seven weeks later the woman was delivered of a second living child, a female, weighing nine pounds, much more vigorous than her mate. In the second case, after a natural labor of a few hours, a living male child was delivered, eighteen inches in length, and weighing seven pounds. Two days later labor pains returned, and forty-nine and one-half hours after the first birth the second took place. The second child, a female, was alive, and measured nineteen inches in length, and weighed seven and a half pounds.

Cerebritis with Effusion.—Dr. Albert E. Sterne of Indianapolis expressed the opinion that cerebritis exudativa was a real pathological entity caused by toxemia; that it occurred in diffuse non-suppurative forms, and that it presented the typical clinical syndrome characterized by extreme physical debility, with peculiarly irregular heart action and rapid breathing, practically without fever, associated with profound psychic inertia and confusion, dissociation of the cortical centers, disorientation and with marked effect upon memory and memory images, but that under careful, proper management the prognosis was very much better than the general aspect of the case often warranted one in believing.

Enteroptosis.—Dr. Alexander C. Wiener of Chicago stated that the therapy of enteroptosis was based upon its etiology. Therapy was composed of three factors: 1. Biological treatment of the underlying causes of the deformities of the thorax and spine. This was done by injections of tuberculin. The other routine hygienic measures adopted and proved by the medical profession were religiously carried out. 2. Mechanical treatment. All deformities of the spine were corrected. The narrow upper aperture of the thorax which found its clinical expression in deep hollows above and below the clavicle was widened out with rubber elastics fastened to the body by means of adhesive plaster. A large percentage of enteroptotic women suffered from chronic uterine catarrh, with tenacious leucorrhea. He had noticed that a veritable flood of a watery discharge occurred in the wake of an injection of tuberculin, and that in time the leucorrhea ceased without any local treatment. Resection of the cartilaginous part of the first and second ribs, as suggested by Freund, to make room for the expansion of the apex of the lung to do away with this favorite nesting place of the tubercle bacilli was not indicated in individuals under fifty-five years of age, for the reason that rubber extension did the same work with much more safety and permanency. The deformities of the thorax leading to enteroptosis concerned the family physician. Enteroptotic patients represented a biological and mechanical unit. Specialistic treatment of the various symptoms must therefore be a failure, even though there was not one branch which was not represented in the pathology of enteroptosis. Permanent success could only be had by a skillful combination of biological and mechanical and hygienic treatment.

The Treatment of Movable Kidney.—Dr. William Billington of Birmingham, England, said that nephroptosis and the problems associated with it had engaged his close attention for upward of six years, and during that time many hundreds of patients had passed under his observation. Upon 345 of these he had operated for mobility of one or both kidneys, and had performed more than 500 fixation operations. In many instances he had tried the effect of mechanical support prior to nephropexy. Amelioration of symptoms, when the kidney was efficiently supported, was a strong argument in favor of nephropexy, should the belt fail to give complete relief or be too irksome for permanent employment. Congenital cases of general visceroptosis were unsuitable for operation. Open operation alone insured permanent and complete cure of renal mobility. Nephropexy could now be carried out with safety, precision, and permanent success, and there were no surgical reasons why it should not be done in suitable cases. The operation was analogous in all respects to the radical cure of hernia, the same general rules applying to each procedure. Given a patient whose symptoms demanded treatment for mobile kidney, the choice between belts and trusses or operation would be determined by the type of displacement, the nature of the symptoms, and the age, occupation, and general condition of the patient. The

greater difficulty experienced in controlling a movable kidney than a hernia by external means (mechanical) made the argument in favor of operation stronger in the former case than in the latter, if considered purely on surgical grounds. The kidney could be accurately replaced in its normal position through the lumbar incision. With regard to his surgical results he had to report three deaths from among 345 patients, a mortality of less than 1 per cent. In 166 of the 345 patients one kidney only was operated upon, while in 179 both kidneys were fixed at the same sitting. The total number of nephropexies was 524. Of the single operation, 130 were upon the right kidney, and 36 upon the left. Thirty-three of the patients were males and 312 females. Of the latter 148 were married and 164 single. His youngest patient was a boy of 14 and his oldest a lady of seventy who suffered from agonizing pains in the right side on the least exertion, the cause of the pain being torsion of the right renal pedicle. Most of his patients were between thirty-five and forty-five, but his experience had been that no period of life was altogether immune from the more serious troubles associated with nephroptosis. He emphasized the fact that the surgical treatment of nephroptosis was now attended with no special difficulties or dangers and could be carried out as safely and successfully as the cure of hernia.

Nephroptosis: Its Effect upon the Nervous System, with Special Reference to Insanity.—Dr. C. W. Suckling of Birmingham, England, said that his paper was based upon twenty years' work on the subject and upon the observation of over four hundred nephropexies performed upon 303 of his private patients. He was astounded at the frequency with which he found dropped kidney, about 40 per cent. among the women suffering with it. He could not help associating the dropped condition of the kidneys with the nervous trouble of which the people complained. He tried various kidney belts, but found they did not keep the kidneys up. He had now had at least 300 cases operated upon. He had seen the kidneys and had observed the changes that took place with age. He had seen the normal kidney, the suprarenal capsules occasionally, but very rarely, descending with the kidney, the colon dragged out with the movable kidney, also the duodenum. He had also seen ptosis of the spleen with nephroptosis. He had visited these patients after nephropexy and had observed the wonderful change in their appearance after a few days. Forty-three of his cases of insanity treated by nephropexy were cured, and five were failures, and two were so owing to bad nephropexy. The technique of the operation was described in detail.

The Etiology of Visceroptosis with Special Reference to the Pregnancy Factor.—Dr. Carey Culbertson of Chicago said that in his paper he emphasized the importance of pregnancy as the factor underlying the visceral prolapsus where the abdominal wall had been permanently insufficient as a supporting structure. The structure of this wall from a physiological point of view was explained, and the changes occurring in it subsequent to the distention of gestation were detailed. Stress was laid on the post-partum changes analogous to involution in the uterus. Throughout it was shown that the muscular and fascial layers were the important elements and that these were more or less permanently relaxed and separated in multiparæ, especially where such women passed through pregnancy and labor at too frequent intervals. The question of intraabdominal pressure was barely touched upon. The pelvic floor was almost equally to blame, as relaxations here were the rule in multiparæ. Herniation here relieved pressure against the abdominal wall, but permitted both abdominal and pelvic organs to sag. Oppositely, relaxation of the anterior wall would permit even an impaired floor to sustain its pelvic organs in position, although the abdominal ones sagged as before. The crucial time for either support was when the woman got up after childbed, the visceral mass being then suddenly projected downward until it found support. Then began the pull on the peritoneal attachments and ligamentary structures which stretched just as far as supporting structures would sag away. It was next shown that the degree of relaxation was increased by repeated pregnancy and in gestation associated with other predisposing factors. Hard labor during pregnancy aggravated the distention already existing as did improper dress, although the latter was seen at its worst at the time the patient again assumed the upright position in the puerperium. The influence of adiposity and gastrointestinal complications, particularly constipation, was emphasized, as was that of coincidental abdominopelvic tumors and ascites. The respiratory disturbances, due to chronic bronchitis and asthma and tuberculosis, where coughing was present, formed an unfortunate complication. In the emaciation and general weakness characterizing the wasting diseases pregnancy found an association that brought the abdominal wall to the limit of its capacity as a supporting structure. Here child-bearing was merely an ultimate factor in a series of conditions, normal and abnormal, any one of which might be etiologically sufficient.

The Mechanical, Nonsurgical, and Medicinal Treatment of Splanchnoptosis.—Dr. A. Ernest Gallant of New York stated that in Glenard's disease there was a synchronous descent of all the viscera, abdominal and thoracic, as well as pelvic, although oftentimes not to a palpable, measurable, or demonstrable degree. In reiterating the principles of treatment laid down in 1901 he advocated, first, replacement and relief by the recumbent, and inclined postures, and manipulation. Second, retention and support by a special corset put on in the semiopisthotonous posture. Third, reparation by local and surgical measures applied to the pelvic organs, the eyes, nose, and throat, etc. Fourth, recuperation by rest cure, massage, exercise, and drugs. Fifth, prevention by use of this corset from the first at puberty, during pregnancy, the puerperium, after celiotomy and ventral hernia. Of the 510 cases under review there were prolapse of the kidney only in 216 cases; kidney and dilated stomach, 130 cases; kidney and stomach ptosis, 55 cases; dilated stomach only, 99 cases. The ages ranged from 18 to 68 years. There were 199 nulliparæ and 311 multiparæ. Of the notable conditions relieved there were 16 kidney relapses after nephropexy; three ventral hernias; 3 separation of the recti; 3 painful ventral fixations; 27 movable kidney jaundice; 4 movable liver; 21 traumatic movable kidneys; 1 fracture of the symphysis pubis during pregnancy; 19 postpartum; and several after wearing belts, binders, plasters, pads, etc.

Principles Underlying the Treatment of Visceroptosis.—Dr. William MacI. Thompson of Chicago pointed out that the principles of pelvic repair were (1) restoration of function; (2) avoidance of scar tissue; (3) accurate approximation of muscles and ligaments; (4) the end results should restore the uterus to its normal position with the intestines on its posterior surface. The rectum should be replaced, and one should separate the too high attachment of vagina and rectum. After the menopause a wider operative field was possible. The satisfactory end results of an operation depended upon a successful initial study of the causation of the individual ptosis and its relation to the neurasthenic. Neither the anatomical standard nor the *x*-ray picture was to serve as a criterion for the operation. There was a similarity between a joint and the muscles moving the joint and the skin over it to the muscles of the trunk and the viscera. If the sympathetic nerves were but visceral ends of the spinal cord, then the muscles and fascia of the abdomen were affected in disease of its contents as were the muscles and ligaments of the joints.

Ovarian and Uterine Tumors Complicating Pregnancy.—Dr. Channing W. Barrett of Chicago presented the following conclusions, which were based on sixty-two cases collected from the literature, four of which were operated on by himself: 1. That, while fibroids and ovarian tumors produced a certain percentage of sterility, pregnancy frequently took place. 2. That with the onset of pregnancy we had two patients to contend with, with a pathological condition, rather than one patient with two pathological conditions, each with claims upon their constitutional rights to life, liberty, and the pursuit of happiness. 3. That the growth of the ovum produced such changes in position and structure of ovarian tumors as to make it a menace to the child and mother in many instances, that extra hazards occurred during labor, and to the mother during the puerperium. 4. That induced abortion, with its 100 per cent. of child mortality, was unjustifiable in that it offered no corresponding improvement in the condition of the mother. 5. The early removal of the tumor as soon as possible, when discovered, gave rise to a high percentage of good results in both mother and child, and removed the hazards during labor and the puerperium. 6. That tapping or puncture of a tumor showed too large a mortality to make it a justifiable treatment except as a preliminary expedient in rare cases. 7. A patient in labor with a complicating tumor should be placed in the most favorable surroundings possible, and labor allowed to terminate, if unobstructed. This should be facilitated by the use of forceps, if labor was at all difficult, and the tumor located well above the pelvis. 8. Tumors interfering with labor pains, or located so as to obstruct, or in a condition of torsion, hemorrhage, or suppuration, so as to offer immediate abdominal complications, might be operated on immediately, with cesarean section, or if the outlet was inadequate, as shown by previous easy labors or by liberal measurements and the soft parts well dilated, the labor might be allowed to continue. 9. Vaginal cesarean section might be performed in some instances of inertia. 10. Vaginal punctures of the obstructing tumor might rarely be permissible, but should be followed by vaginal or abdominal removal before or after labor, as punctures, with nonremoval, showed a high mortality. 11. Surgical dealing with fibroids during pregnancy showed such a percentage of recoveries from myomectomy as to warrant its use in cases presenting symptoms. 12. Cases of fibroid tumors, complicating pregnancy, but presenting no untoward symptoms, should be treated expectantly as a myomectomy, might end in a hysterectomy, or result in abortion. 13. Hysterectomy or abortion, with its necessary 100 per cent. mortality to the child, was unwarranted in cases without symptoms. 14. In all operative procedures, during pregnancy, great care should be taken in manipulating the uterus.

Treatment of General Peritonitis, Based Upon Personal Experience.—Dr. Daniel N. Eisendrath of Chicago reported thirty-two cases in seven years with three deaths; twenty-two in the past three years, with two deaths. The causes of death were acute dilatation of the stomach, general sepsis and uremia in one case, phlegmon of abdominal wall in another, and initial general sepsis in the third. One additional case that died of pneumonia one month after operation had been well and up for nearly two weeks. There were ten cases operated on the first day, with no deaths; twelve on the second day, with one death; seven on the third day, with one death. In the majority of cases there were no previous attacks due to the organ involved. The most valuable symptoms were increase in pulse rate, spreading rigidity and tenderness, persistent nausea and vomiting; uncertain signs of the presence of fluid and absence of liver dullness. The distention came on too late, as a rule, to be of much value. Fever also was not reliable. The white blood count was increased in all cases, except the most severe ones. Urinary findings were of importance in regard to prognosis. The peritoneal changes were typical in all cases. In twenty appendicitis cases there was a visible perforation. In eight there was none. The latter class of cases were just beginning to be recognized. Peritonitis was general so far as he could see. After describing the technique of the operation, Dr. Eisendrath drew the following conclusions: 1. We could greatly reduce the mortality of peritonitis if we were able to get the cases early before the septic intoxication was too far advanced. 2. Our first consideration must be to seal up the source of infection and thus check the further inflow of infectious material into the peritoneal cavity. 3. A minimum amount of interference and rapid operating, followed by proper drainage, were the keynotes to success. 4. The natural resistance powers of the peritoneum could be relied upon for much aid if we did not burden them with too much to be taken care of. 5. The drainage could be best secured through a suprapubic incision made after closing up the source of infection. 6. Constant vigilance after the operation was necessary to steer through the rough waters of possible postoperative complications. The principal ones were dilatation of the stomach, abscesses between the coils, nephritis, and ileus. 7. It was unnecessary to get rid of all pus during the operation. By drainage at the proper point, elevation of the head of the bed, we reestablished normal pressure relations and favored drainage.

The following papers were also read: "Comparative Teaching Value of Photographs and Drawings in the Technique of Hernia," by Dr. Charles T. Souther, Cincinnati; "Treatment of Hemorrhage in Pulmonary Tuberculosis," by Dr. Charles L. Minor, Asheville, N. C.

Officers.—The following officers were elected for the ensuing year: *President*, Dr. Louis Frank, Louisville, Ky.; *First Vice-President*, Dr. Albert E. Sterne, Indianapolis, Ind.; *Second Vice-President*, Dr. William Werner, Joliet, Ill.; *Secretary*, Dr. Henry E. Tuley, Louisville, Ky.; *Treasurer*, Dr. Samuel C. Stanton, Chicago. Chicago, Ill., was selected as the place for holding the next annual meeting in October, 1912.

Simultaneous Bilateral Tubal Pregnancies.—Vautrin thinks that conception with the ovum in the tube instead of the uterus is quite a common occurrence, and that in most cases the ovum passes on into the uterus; when it does not do so it is either absorbed after death due to lack of proper circulation and nutrition, or causes a tubal abortion, which before three months is characterized by a few abdominal pains and a moderate intermenstrual flow. The ovum remains permanently fixed in the tube by an unusual combination of circumstances. The cause we do not know, since inflammation and alterations of the tubal walls do not seem to play an important part in causation. Pregnancy may develop in both tubes at about the same time, and here we are not justified in sterilizing the patient because she is so unfortunate as to have a first abnormal conception. After four months the tubal pregnancy exposes to greater dangers, to hematocele, which may become infected. A non-infected hematocele may be allowed to remain, in hope of absorption. An infected one demands posterior colpotomy and drainage. Infection of the tube may cause salpingo-oophoritis, displacements and sclerosis. After the removal of the ovum by tubal abortion the envelopes may become encysted in the tube by closure of its extremities and become a hard tumor. When the ovum is retained laparotomy may be necessary and then hysterectomy is justifiable. But when there is a double infected hematocele one need not necessarily do a laparotomy, but should give the patient the benefit of a colpotomy, with a possible later normal pregnancy.—*La Gynécologie.*

Medicolegal Notes.

Injunction Against Unlicensed Asylums.—Where a statute prohibiting the establishment of asylums or retreats for the care of the insane or persons of unsound mind for compensation and hire, without first obtaining a license from the State Board of Charities, is continuously violated by receiving, keeping, maintaining, and caring for persons of the classes named in an unlicensed asylum or retreat, thereby causing fear, consternation, and disturbance of the peace in the community, an injunction may properly be granted to restrain such unlawful acts, and the court is not restricted to a prohibition of disturbance of the peace. State v. Lindsay, Kansas Supreme Court, 116 Pac. 207.

In a proceeding for contempt in violating such an injunction, the evidence of a witness that screams from the cottages which she described made her nervous and disturbed her was admissible, a party being competent to testify to his own mental condition.—State v. Lindsay, 116 Pac. 209.

Corporation Not Liable for Its Surgeon's Malpractice.—A passenger who had sustained injuries in alighting from a street railway car and who had been treated by the company's surgeon sued the company for damages, averring that the surgeon's diagnosis was improper and his advice and treatment incorrect, resulting in his being made a cripple. In affirming a judgment for the defendant it was held that a contract to perform medical or surgical services by a corporation organized for the purpose of constructing, owning, and operating a street railway is not only ultra vires, but is in direct conflict with the laws of the State of Ohio regulating the practice of medicine and surgery, and is, therefore, void. Such a corporation cannot be directly liable for damages for malpractice of medicine or surgery. It may make a valid contract to furnish or pay for medical aid and attention to one injured upon its cars or tracks. A petition averring the making of such a contract, the employment by the company of a surgeon in pursuance of the contract, and malpractice on the part of such surgeon resulting in damages to the plaintiff, but which does not aver that the person so employed was not regularly admitted to practice medicine and surgery in the State, or that he was incompetent and the company knew, or had means of knowing, of his incompetency, or that it was otherwise guilty of negligence or carelessness in selecting him to perform such service, does not state a cause of action.—Youngstown Park and Falls St. Ry. Co. v. Kessler, Ohio Supreme Court, 95 N. E. 509.

Charging Fees from Patients Does Not Change Public Character of Municipality's Hospital.—A petition in a suit for personal damages alleged that the plaintiff was injured in consequence of being struck by an ambulance which was negligently driven against him while he was in the exercise of due care, and that the ambulance belonged to and was being operated for a public hospital of a municipal corporation which was under the control of the municipality through its board of officers. It averred that in the maintenance of the hospital the municipality "charged fees for patients entering therein." It was held that this last averment was not tantamount to an allegation that the municipality maintained and operated the hospital for pecuniary gain and private profit, and the petition was demurrable. For the hospital to charge fees from some of its patients would not be inconsistent with its character as a public institution and one operated by the municipal corporation in the performance of its governmental duties.—Watson v. City of Atlanta, Georgia Supreme Court, 71 S. E. 664.

Waiver of Physician's Privilege Not to Testify.—In an action for personal injuries the plaintiff's counsel criticized a physician who was a witness for the defendant and had performed operations on the plaintiff before the injury for failing to avail himself of his privilege and for testifying over the plaintiff's objection as to the effect of these operations. The court charged that the physician had done nothing for which he should be criticized, and that there were many extenuating circumstances why the physician had stated the condition of things which he had discovered, so that it was well to use charity in viewing the acts of all the parties connected with the case. The defendant's counsel excepted to these remarks on the ground that, as the witness had the absolute right to give the fact and truth and the defendant had the absolute right to elicit these, the witness needed no charity, and his testimony was not open to criticism. It was held that the trial judge's remarks were not open to this exception in the Court of Appeals.—Cross v. City of Syracuse, New York Court of Appeals, 94 N. E. 184.

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ended December 2, 1911:

	Cases	Deaths
Tuberculosis Pulmonalis	354	158
Diphtheria	224	24
Measles	253	1
Scarlet Fever	163	4
Smallpox	1	1
Varicella	188	—
Typhoid Fever	81	13
Whooping Cough	36	3
Cerebrospinal Meningitis	1	1
Malarial Fever	—	—
Totals	1,301	205

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended December 1, 1911:

THE PUBLIC AND THE MEDICAL PROFESSION.*

BY JAMES EWING, A.M., M.D.,

NEW YORK.

PROFESSOR OF PATHOLOGY, CORNELL UNIVERSITY MEDICAL COLLEGE.

TO-NIGHT the New York Academy of Medicine enters formally upon the sixty-fourth year of its activities. It was in 1847 that one hundred and thirty-two New York doctors, led by John Stearns, A. H. Stevens, Valentine Mott, and Isaac Wood, resolved to incorporate the higher interests of the medical profession in the New York Academy of Medicine. The objects in mind at that time were mainly three: (1) The unification of the regular practitioners of medicine, (2) The elevation of the standard of medical education, and (3) The promotion of the interests of medical science.

The strong ideals of those early days far outshone the modesty of their organization, for, as Dr. William Detmold recalled many years later, the early meetings of the Academy were held in a dingy room over a coal yard in Wooster street; the social ambitions of the new institution were most meager; not even a beginning of a library was attempted; and the idea of a permanent building, which was sorely needed for the various uses of the institution, seemed and proved to be a far distant dream.

The foundations of a permanent building fund were laid in 1853 when the surplus contributions of the doctors for the entertainment of the American Medical Association were set apart for that purpose. Yet it was only after an interval of twenty-two years and through oft-repeated efforts that in 1875 the Academy was able to purchase a home at 12 West Thirty-first street. A notable ceremony marked the occupation of this first permanent building of the Academy, and the addresses on that occasion revealed what strenuous efforts and almost religious enthusiasm had been called forth in the endeavor to provide a great community with a home for its Academy of Medicine. The fervent pioneer spirit of the founders of the Academy is well displayed in the words of John Stearns, who in an early address declared that if he could be assured of its uninterrupted and enduring prosperity in disseminating health and happiness and the sustaining principle of life he would die in peace with effusions of gratitude and praise to Almighty God for his permanent blessings upon their labors.

It does not appear that the founders of the Academy received or looked for any material support from the public. Both the fruitless and the successful appeals that in 1875 had accumulated $14,000 had been made exclusively by the three hundred members of the Academy itself. Likewise in the further material growth which led to the purchase of the present site and has brought us to-day to the necessity of extensive enlargements of the Academy building, the appeal has been, with a few noteworthy exceptions, to the medical profession itself. A glance at our sister communities shows that the history of the New York Academy of Medicine is being or has been reproduced in many other American cities. Everywhere the demands of the higher ideals of medicine lead to the creation of such institutions, and everywhere the appeal is met chiefly or wholly by the medical profession.

Throughout the long period of our material growth the intellectual activities of this Academy have more than maintained an equal pace.

The 132 original members have been succeeded by the present membership of 1,280. While it is becoming less and less a mark of distinction to be a Fellow of the Academy, it is more and more a notable delinquency for an eligible physician not to become a member. The single section of the early days has expanded into a score of special bodies, each pursuing effectively its special field in regular conferences. The general meetings of the Academy draw the most distinguished representatives in America of every branch of medical art. The interests of every branch of medical science are warmly supported by the authorities of the Academy, and here have centered the activities of several independent medical organizations, some of which, as the New York Pathological Society and the County Medical Society, are more venerable than the Academy itself, and our hospitality is sought by several bodies representing allied sciences and arts. Scores of distinguished visitors from abroad remember and many have recorded their welcome here. The records of the Academy show that from the earliest days the best work and the best thought of the leaders in New York medicine have been presented at its meetings, and those who are familiar with the submerged history of the Academy know that its life has always depended upon the unfaltering devotion of a long list of famous physicians who have planned and worked for its interests.

Yet the scope of the Academy is not confined to the current activities of its various sections and allied societies. The library of the Academy has been the special pride of many of the foresighted guardians of the past, and is to-day the second most complete collection of medical literature in America. It is freely accessible not only to the entire medical profession but to the general public as well, and it is probably the most actively used collection of books in the world. It would be difficult to estimate the significance of the influence thus exerted, through the dissemination of knowledge, not only in all branches of the medical profession, but also in veterinary science, dentistry, biology and chemistry, and in the steadily enlarging scope of the

*Anniversary address of the New York Academy of Medicine, delivered November 16, 1911.

layman's acquaintance with medicine. May we not pause and compare with pride the relative significance of this priceless collection of books stored in dark corners with that of our magnificent and aristocratic neighbor the New York Public Library?

The public services of the Academy extend, also, to the consideration and support of the interests of hygiene and sanitation and many peculiar problems of sociology and public morals, which can be solved only through intimate acquaintance with their medical aspects.

Truly Medicine is still the Mother of the Sciences, and the Academy of Medicine in New York has established itself as the home and guiding hand of all the influences which, according to worthy tradition and critical experience, further the realization of the ideals of the medical profession. It would be a worthy task, in which one might engage with enthusiasm, to fully sketch the history and present position of the New York Academy of Medicine, for this we believe is a fair reflection of the best type of medical enterprise. The profession is proud of the Academy and asks that the leading motives of medicine be judged by the standards established here.

But I have only hinted at some of the conspicuous achievements of the Academy in order to introduce the subject of this discourse, which is, not what estimate we place upon ourselves, but what conception the public holds of modern medicine.

Our distinguished President, in honoring me with the task of preparing this anniversary address, has doubtless acted in accordance with the growing tendency to dispense with an orator and an oration and to call on these occasions for a specific treatment of some of the many problems that confront us. Being thus relieved of the necessity of attempting a literary contribution I have ventured to think that the present somewhat delicate topic might well engage the attention of this audience. For there is no denying the fact that the public holds quite a different conception of medicine from that of the physician, that there is a growing distrust of medical practice and an increasing dissatisfaction with its results, that disclosures of grave defects in the standards of medical education, which we freely admit, have mystified the public and raised a serious suspicion regarding the general competency of practitioners, that increasing specialization and the increasing cost of medical services are misinterpreted, and, above all, that the striking achievements of the mechanical arts, the increase in wealth and luxurious living, have rendered more conspicuous than ever before the uncertain tenure of human life and the incompetency of modern medicine to control the great majority of diseases. In the presence of these obvious conditions, which every order of intelligence can appreciate, there is perhaps little wonder that the public passes with perfunctory notice the brilliant conquests of preventive medicine, ignores the rapid advances in the general knowledge of biology, physiology, and pathology, and permits an event like the discovery of *Spirochæta pallida*, an agent that has had a very profound influence on human history, to pass without even the faintest sign of public attention.

It is not intended to suggest that all educated laymen are unfamiliar with the true progress and achievements of modern medicine, but it is nevertheless true that prevailing public sentiment is out of touch and out of sympathy with us. This is seen in the crude and halting manner in which medical topics are handled by distinguished writers, clergymen, lawyers, statesmen, and public officials. It appears in the garbled references with which the most inspired of the Press condescend to honor us and misinform their readers. It shows in the liberal public support of all manner of medical cults, in the wide extension of the Christian Science movement, and in the wavering front of legislature which no longer stands as a firm defense of the public health against the depredations of irregular and incompetent practitioners of medicine. Even the trustees of a great university yield to the allurements of a questionable interest, backed by a paltry sum, which seeks to encroach upon a most delicate and difficult medical specialty. Quite significant it appears also that the stage lends itself to our disapproval, by burlesquing the discovery of a most notable and beneficent addition to modern therapeutics, and garnishing the entertainment with catchy reference to the dilemma which every doctor faces when he charges a fee for saving human life. Truly the wide extent of this public distrust must be acknowledged, the grounds for it should be carefully analyzed, and we must soberly ask the question, Is the medical profession doing its full duty to the public? James Russell Wallace once said, in effect, that an institution once established may come to be the chief obstacle in the way of the satisfaction of the need for which it was established. Wallace made this criticism of the Church. Does it apply to medicine? Have we stood too confidently on the record of progress of the last sixty years, for modern medicine is only about sixty years old, and failed to realize that even greater achievements were within our reach; have we pursued science too much for science' sake and too little for its influence on human life; has the old, almost sacramental and heroic, character of medical service fallen before the advance of commercialism; is the Hippocratic oath still the standard of medical ethics; is medical science, as the chief influence which makes for the subordination of physical evil, acquitting itself well in this day and generation, or are other sciences and professions outstripping us and do we deserve the disaffection and diffidence with which, on the whole, public sentiment regards us?

I can only offer some general considerations that bear upon these broad topics, and in doing so it is frankly acknowledged that I appear as an advocate in defense of medicine, and even with specific charges to prefer against the public, and I think this course may be justified on the ground that good may come from a frank statement of what the public owes to the medical profession.

In the last analysis the public disaffection with medicine rests upon an inherent defect of the human mind which opposes correct thinking along medical lines. When one reflects that even the leaders of medical thought for more than a thousand years passively bore the yoke of Galen's crude conceptions, of the pneuma, and the four cardinal principles of the body, blood, mucus, yellow and black bile, conceptions that correspond to nothing of importance in physiology, and that these conceptions held sway at the height of the development of Greek and Roman literature, law, and philosophy, it would seem that the human mind is constitutionally unfitted for the grasp of biological principles. In this quality the public intelligence of to-day has advanced but little over the standard

of the ancients. Whether it be from mental deficiency, or from a deeply rooted remnant of superstition so rife in all common people, or from a possible narrowing influence of a portion of the Church, or be it the educational system of the last centuries with its schooling in rigid mathematics and speculations in philosophy, whatever the cause, the modern mind is unfitted to grasp the idea of the marvelous delicacy and infinite variations of biological processes, and, therefore, it does not understand medicine.

Consequently, throughout its entire history, medical science has occupied an isolated position apart from the better understood and more cordially approved pursuits of mankind. It was not alone in punishment for his fatal results that the medieval surgeon had to leave town after each operation and lead the life of a nomad. It was a truthful expression of the public doubt of the honesty of the calling of the surgeon and a superstitious fear that the successful physician worked by supernatural methods. Naturally the protection of the Church was a ready resort of the physician, and medicine and ecclesiasticism long worked in a certain harmony, medicine always shielded by the cloak of the priest. This unnatural union, enforced by public sentiment, led to the centuries of reliance upon the healing power of the saints and their relics, a situation distinctly fitting the public taste, but it led to the suppression of rational thinking and experiment, things which did not suit the public taste. Accordingly Friedrich Muller says that "The darkest periods of decay in German medicine were those in which philosophical speculation and theological mysticism obtained a preponderating influence over medical problems." (Royal Com. on Univ. Education, June 30, 1911.) As degenerative phases of this movement we have the long history of sorcery, necromancy, astrology, and alchemy, all of which flourished in response to the demand of an uninformed public sentiment. The Church has been held responsible for much of the suppression of medieval medicine, but from this point of view it might appear that the public and not the Church was essentially at fault. The dissection of the human body, needless to say, was distasteful to public sentiment and the foundations of human anatomy had to be laid while the public were protesting. The antivivisection movement throughout its long history falls in the same category of public movements founded on misconceptions of medicine. The conflict between science and religion was another expression of the same tendency. I believe that careful historical research would reveal many familiar facts of history which could be cited and interpreted to show that the public has never understood its contemporary medicine.

Would it not, therefore, be good policy if the more enlightened public of to-day should analyze the grounds of its disaffection and make sure that history is not repeating itself and that persistent traces of the old prejudice do not lie at the bottom of the current distrust of medical institutions? Only a few months ago thousands of excited people gathered around the relics of a departed saint in the eager hope of receiving some of their supposed healing virtue. There are many sides to the significance of the Christian Science movement, as William James has shown, but so far as it is an intelligible doctrine, and not mysticism, it rests chiefly on ignorance and distrust of medical science. We must confess that the public patronage of the numerous medical cults is logically due to the failure of medicine to deal successfully with a host of minor ailments. Physicians can well afford to yield to osteopaths and hypnotists the immediate concern with a long list of self-limiting functional disorders, but the public cannot afford thus to intrust to any but physicians the early stages of serious disease. Here the public makes the further blunder of ranking with serious interests of medicine that host of abnormal sensations, some of them painful, which fall to the lot of the overfed and the indolent.

The most familiar sign of the public misconception of medicine is displayed in the efforts of the daily press to furnish information on medical topics. With rare exceptions these efforts consist of sensationalism, personalities, wonder-tales, absurdities, and a general display of the haste and incompetence of the writer. Every medical article written for the public press should first be submitted to a competent medical expert for revision. More pernicious still is the influence of a score of semi-medical journals which cater to the taste for misinformation and absorb a large portion of the $50,000,000 paid annually in this country in the advertisement of quack medicines.

The public has heard that medicine is highly specialized, but has not yet learned that specialization does not immediately transform the average general practitioner into a highly competent expert in a narrower field. The clever lawyer still takes pride in demonstrating that the experienced manager of an insane asylum may not be an expert in psychiatry. The courts accept practically any holder of a medical degree as a trustworthy authority in any department of medicine with which he chooses to claim acquaintance. It is very rare to find even an educated layman who understands that the medical sciences stand somewhat apart from practice and that they comprise a numerous group of highly specialized branches, each requiring peculiar training and attainments. For the educated public the opinion of Robert Koch is only in a vague way a little better than that of their family doctor, while the uneducated public does not concern itself with the opinions of scientists. Here is the great dilemma. Medicine is like the iceberg, seven-eighths of which is submerged, but the public must of necessity form its estimate from the visible one-eighth.

Not having understood medicine, public sentiment has never given it adequate material support. That support has come from enlightened governments and from men of large means and discerning minds. The numerous private endowments of medical philanthropy and research in this and other countries stand as a conspicuous ornament in modern life. Yet these gifts have come from isolated sources, they are usually impelled by the occurrence of some tragedy in the family of the donor, only in a few notable instances have they arisen from a clear conception of the needs and deserts of medicine, and they do not constitute uniform and adequate public support. Even in this, which is the best expression of the public conscience, too often the institutions have been isolated, diminutive, and ineffective, and it must be feared that occasionally they have served chiefly to exploit the donor and the donor's physician. It is clear that the type of almsgiving counseled in the Sermon on the Mount does not meet the exigencies of modern life. Medicine cannot afford to rely too much on the generosity of public-spirited citizens.

It is, therefore, a significant sign and an honor to the intelligence of our Western States that their Legislatures have adopted the policy of caring for medical education and research. A considerable volume of public opinion is back of this policy and the Western people are proud especially of the assured future of their universities. To what extent medicine will flourish under these auspices remains to be seen, but at present the West as well as the East has a wholly inadequate idea of the scope and cost of medical education and research.

Perhaps the surest expression of public sentiment is found in the character of its legislation. I think it must be said that the laws of the land protect the medical profession better than the public. There has been a notable disinclination to restrict the rights and privileges of the regular school of medicine, but there has been, on the other hand, an ill-considered expansion of the privileges of irregular practitioners and semimedical cults. In this liberality the public sees only adherence to our traditional ideas of freedom, but it does not see at what cost of life it has legalized the treatment of all sorts of disease and the signing of death certificates by uninstructed persons.

In the adoption of the measures which medical science has demonstrated as necessary for the protection of public health most American communities are delinquent. There is not a single active school of sanitary science in the country, not because the universities have not tried to establish them, but because there is no demand for them and there are no students. Therefore, the sanitary laws of small communities are enforced by persons who are often interested in their infraction. In many cities typhoid fever has been epidemic for years, although these communities were fully able to build water filters. Medical science has pointed the way almost to the complete suppression of tuberculosis, but tons of tuberculous beef are marketed in New York daily, and the average dairyman thinks his opinion of the tuberculin test in cattle is quite as good as that of the German Government. It is said that the inhabitants of Southern States generally resent the gift of a million dollars to build sanitary waterclosets and help rid them of the hook-worm. Indeed, it is the usual experience for the public to resist the introduction of sanitary measures, so that it has been necessary for medicine not only to perfect these beneficent measures but also to bind the beneficiaries hand and foot in order to administer the remedy.

It is not alone the pressure of politics or the eccentricities of the Law which delay the formation of at least one institute of legal medicine in this country. It is the general failure to appreciate that a high development of this branch of medicine is essential in a well ordered community. The National Government has at last awakened to the necessity of a National Bureau of Health, such as has long existed in other civilized countries. Yet instead of going ahead with it we have the astonishing spectacle of the President of the United States holding a public hearing to debate the question. Finally public sentiment still permits the Health Commissioner of the State of New York to be replaced every few years according to the rules of political patronage, and with Asiatic cholera at our doors we have just witnessed the distinguished Health Officer of the Port of New York subjected to an investigation by a medically uninformed jurist to whose mathematical mind the control of an epidemic must be "either efficient or inefficient."

Such is a partial catalog of the delinquencies which modern medicine charges up against the modern public. In enumerating them I fully realize that they relate chiefly to deep currents of opinion, thought, and custom, which move with great momentum and are beyond the control of pure authority. Yet they do not concern isolated eddies in the current of opinion, but fairly reflect the general tendency and color of public feeling. Certainly there is here enough undigested food for thought to fully occupy the attention of the layman and to call for a concerted effort to render public sentiment more considerate of its plain responsibilities. To quote again from Wallace, "the nineteenth century added to the sum of human knowledge more than the previous ten, but did less than any other to make its knowledge available for human needs." Medicine has done its duty to the public, but the genius of medicine is not understood and the problems which medical science has laid at the door of the modern world have not been adequately acknowledged.

There are other duties besides those which we are obliged and enabled to perform because of the general progress of knowledge. The modern spirit of service demands that medicine shall not overemphasize the achievements of the past, but should adequately prepare for the future. The objects for which this Academy was founded are just as urgent to-day as in 1847. The unification and morale of the regular profession rightly engage our constant attention, and, while we acknowledge the justice of outside criticism of the streaks of commercialism and veins of mutual distrust which may afflict us, strong internal forces are at work, to combat these tendencies. No commercial physician escapes detection and the right estimate by his fellows, and medical opinion places a far higher value upon just valuation than upon clever criticism of the work and attainments of one's colleagues.

Medical education is the most earnestly considered problem before the profession to-day. The astonishing changes that have occurred here during the last two decades in America have been approached in no other field of human endeavor and stand as a monument to the honesty and intellectual vitality of the American medical profession. As a feature in this progress the fourth Report of the Carnegie Foundation, which was delivered without fear, has clearly stated the situation and hastened many desirable changes. Incidentally this Report carries a message of great significance to the public, since it shows that the so-called regular profession is the only body seriously engaged in medical education and research, all the medical cults which the public loves to patronize standing before that bar of judgment empty-handed or worse.

The third object of this Academy and the duty of the entire profession which it represents is to further the interests of medical science, and it remains as the last part of the plan of this discourse to inquire whether we have done our duty to the ideals of medical science. In making this inquiry we pass far from the ground of common-sense judgments to the field of ethical ideals, but a large part of medicine lies in this latter territory. In these days when the word research is on every man's tongue, when journals teem with titles purporting to relate to new facts in medical science, when the attention of men of means is successfully directed to the re-

sults attainable in this field of philanthropy, it might seem to be a difficult and useless task to argue that the medical profession does not adequately support medical science. Yet this is just the judgment which, with much caution and reserve, I would venture to maintain this evening. I hasten to acknowledge the brilliant record of American men of science in medicine, the long list of notable discoveries and fundamental contributions that represent the best product of American brains. As a pathologist I take pride in belonging to that branch of the profession that produced Ricketts and a score of European martyrs to science. It is true also that a somewhat extensive machinery has been set in motion in this country with the idea of enlarging the scope and raising the standard of our scientific work. There is much to the credit side of the account. Yet a clear conception of the meaning of medical research, the physical conditions under which it can thrive, the organization of institutions that can supply the training and the men, a true estimate of the value of scientific attainments and tendencies in the medical practitioner, in fact a systematic attention to the demands and ideals of medical science are not highly developed in this country, and in this respect medicine, having discharged its duty to the public, is delinquent in its duty to itself.

Having, in a sense, closed the doors to our public critics, I beg leave to briefly state some of the grounds on which this feeling is based.

The misconceptions of the nature of medical research take very numerous forms. One of the most curious was embodied in a recent public document recommending the introduction of the methods of the department store into scientific laboratories, as though, as one commentator retorts, the discoveries of a Newton could be called for at a certain day and hour, or that the scientist's mind should run chiefly in the line of the card catalog of trivial events. Quite rife is the idea that research consists in extracting the European mail, repeating the experiments one finds there, and publishing the results without full acknowledgment of their inspiration, or, what is little better, with a few additional facts which are chiefly dependent on accidental conditions. Many think it necessary to point out minor faults in fundamental contributions, but I very much doubt if such activities are ever worth while. To set oneself the specific task of demolishing the conclusions reached by careful observations of one's colleagues is seldom a necessary step in progress. Agassiz advised "Study Nature, not books." Some investigators announce as many as twenty or even thirty titles of original studies in one year, but Theobald Smith said "the real progress of medicine is covered over with a froth of research through which only a few great minds are capable of penetrating." Opinions differ as to what methods of announcing the progress of research are consistent with sound judgment and a sterling devotion to the best ideals, but there are those who deplore the strife for priority, who distrust the preliminary communication, and who believe that a man is an unsafe man in so far as he is looking for prompt recognition of his contributions to medical science. I mention these somewhat distasteful matters because the opportunity to study carefully the mysteries of disease and to publish the essentially new results at the proper time and in a dignified manner is not so common as some of us may believe. Few would care to offer a definition of genuine medical research, but I think I see examples of the true spirit in men who are very sensitive to the unknown in the medical conditions they meet, who feel a certain moral responsibility toward the solution of problems, and who are willing to spend some or all of their time in the solution of these problems. This type of research is open to every member of the profession.

The discovery of *Spirochæta pallida* was a sensational event, coming apparently out of a clear sky. Yet even here there were several preliminary steps which made this discovery possible. A series of fundamental contributions, usually from many sources, almost always precedes a great discovery, so that the final step is a perfectly logical result of antecedent factors. Are we not inclined to underestimate the value of fundamental contributions in the haste to create medical heroes on the basis of supposed single-handed discoveries? Some find it their function to plant the root of knowledge and cherish the growing tree over many barren years, while others delight to pluck the fruit when it is about ready to drop. It is significant that the credit for great steps in the progress of knowledge can seldom be narrowly placed.

The physical conditions that surround the interests of medical science in this country are comparatively unpropitious. When the financial rewards of most other lines in medicine are distinctly alluring only a vein of eccentricity or idealism can induce a young man of ability to enter a career which assures a comfortable living for but a few fortunate leaders. The president of a great university recently openly announced that it was necessary to fill the ranks of the medical sciences with such eccentric persons who could get along without a decent living, and this is the tacit policy of all American medical schools. As a necessary result, the quality of brains that enters the medical sciences in America is of the nonconformist type and in certain respects is inferior to that which enters practical medicine, but I hasten to add my belief that the superior intellectual life and scientific methods of the laboratory may enable the inferior man eventually to outstrip his more gifted colleague.

In America we boast of our material resources for medical science, but in reality they are far inferior to those available in Germany and France. The Germans paid Waldeyer 140,000 marks a year at Strasburg, besides student fees, but there are very few positions in America which permit a scientist to live in a city house and raise a family. Money rewards do not attract the genuine investigator, but until the endowments of research are on a wholly different scale from the present the true possibilities of American medical science will not be realized.

The organization of our medical institutions could hardly be worse for the progress of science. The three main activities, the care of the sick, the education of physicians, and the search for new facts, have grown up in isolation, although every one recognizes that each is dwarfed without the others. The complex factors which stand in the way of successful reorganization have been clearly stated by recent writers and the public conscience is slowly awakening. The medical schools are beginning to see that they are quite as much responsible to medical science as to medical education, and at least one school is being founded with this responsibility chiefly in view. It becomes increasingly difficult for the busy practitioner to meet the demands of a great department in a university, but

he can perform an honorable service by surrounding himself with young men who have been trained in the sciences upon which his specialty depends for progress. The time has come when those who aspire to a university career or distinction of any kind in the clinical branches must serve an apprenticeship in the medical sciences instead of in the personal service of the influential doctor.

The interests of medical education are in the hands of several very able bodies and its innumerable and very complex problems have been discussed with much care and discernment. Yet I believe that the trend of this discussion indicates that the American profession underestimates the claims of medical science as an ideal in education. Everything is being swept aside in the effort to provide the student with premature clinical experience. We shall doubtless turn out the most adept practitioners in the world, as we do dentists, but dentistry is almost sterile as a science and relies on medicine for its chief progress. It is to be feared that the new curricula discriminate too boldly against that broad acquaintance with the medical sciences which alone can maintain the standards of the profession. We discriminate against knowledge more than Germany undervalves practical ability. We are not yet willing to pay the price of mature and effective clinical instruction, for that price is a fifth year in the medical curriculum.

In the years 1800-1810, or longer, a leading hospital in New York devoted funds to the purchase of expensive medical books and maintained a library for the use of its staff. The trustees seemed to feel a responsibility to medical science. That library has been dissipated and the hospital is now run on strictly business principles. Yet there is venerable precedent for the support of medical science by our great hospital endowments, and it has been made clear to the slumbering conscience of the hospital trustee that he has long been gravely delinquent in an important duty. It will be a notable event in the history of American medicine when that conscience is fully roused to action and when, overcoming every obstacle, there is effective cooperation between the immense resources of our hospitals and those of the universities.

That there are contrary opinions regarding the value of scientific training to the practitioner merely shows how vague is the general conception of laboratory science. It seems to me that this is the most discouraging side of the present outlook for medicine. It is chiefly responsible for the gulf which separates medical science from medical practice, and it accounts for a vast number of the occasions when the right thing is not done at the right time at the bedside. It substitutes empiricism for carefully tested opinion. Not being familiar with the methods and limitations of laboratory technique, the practitioner readily acquires a confidence in the infallibility of diagnostic tests, of which the dead far outnumber the living. Or he affects complete distrust of the whole field of microscopical and chemical diagnosis. It remains the great function of the clinical observer to discern many of the problems of medicine and to suggest to the laboratory those that may be solvable, but this function can be performed only by one who is acquainted with the methods and capacities of laboratory science. Scientific training adds class to the quality of a medical practitioner, and whether we like it or not it is a fact that the well trained man is the productive man in his field and is steadily replacing the untrained. Competition in clinical preferment has not yet reached with us the stage when a record of productive work is essential, but that day is not far distant, and I venture to predict that it will come suddenly and to the sore discomfiture of many of the confident detractors of the value of laboratory training to the practitioner.

Thus several of the most vital interests of medical science suffer from very conspicuous defects in the present support and even in the future plans of the profession. It is not too much to say that medical science flourishes with us in the face of unnatural hindrances, many of which it is within the power of the profession to mitigate or relieve. Some of the conditions would not be tolerated for a moment in the industrial world, and others, such as the obstacles to the scientific development of our hospitals, are incompatible with a plain sense of honor. In certain aspects, as Wallace suspected of the Church, the inertia of our medical institutions and traditions stands in the way of the satisfaction of medical needs. I venture to say that the settled policy of this Academy should involve a systematic campaign in support of the larger interests of medical science. Twenty years ago Max Nordau predicted that in a quarter of a century American medicine would outstrip the world. I fear he is disappointed. We began too late and there are only five years left. Yet five years of the right kind of effort would make a vast difference in the complexion of medical institutions in America.

And finally, may we not anticipate some of the rewards of faithful devotion to the ideals of medical science? We love to dwell on the past conquests of medicine, in the control of epidemics, in the rendering habitable of the uttermost parts of the Earth and the slums of great cities, in the triumphs of surgery on which we drill the public, in the immense advances in chemistry, physiology, and pathology, and in the creation of many new branches of medical science, all of which have combined to add 20 to 25 years to the average tenure of human life, but one may listen to this rehearsal without a particle of emotion when one considers the greater problems that still confront us. The fruits of the germ theory have enabled us to prevent infectious diseases, but our capacity to cure them is extremely limited. In the knowledge of diseases of nutrition and metabolism hardly a beginning has been made. Of the ultimate nature of the physical and chemical processes upon which life and animal functions depend we possess only vague surmises. Before the long list of natural diseases of the animal kingdom we stand as helpless catalogers of superficial phenomena. Medicine is still in its infancy. Comparative medicine is a pigmy opposed to a Colossus of unmeasured proportions. Considering the vast scope of its problems, the activities of our anti-cruelty societies, which are the pride of many, appear as idle splashings on the water's edge of the ocean of animal suffering, while the real depths of that ocean are being sounded by the workers in comparative pathology. One can review only with horror the brutal forms of parasitism and the merciless laws of natural slaughter and death that prevail among the lower animals. It was an observation in natural history when Isaiah said "They shall look unto the earth and find darkness, dimness of anguish." For we are charged with the whole task of mitigating physical evil throughout the entire animal kingdom, and our human interests, as we are beginning to

see, are inextricably bound up with those of the lower animals. We must accept the hope that Nature herself shall some day be redeemed. Medicine is clearly marked as the chief instrument in that redemption and only in the light of this destiny can her true dignity be realized. How then can we rest, even for a moment, on the achievements of the past?

Every period in the progress of medicine is marked by opportunities which render it more significant than its predecessors. At the present time, while no new era in medicine seems imminent, the opportunity for the successful application of known principles to practical questions is unprecedented. No medical heroes rule with unquestioned authority to limit the freedom of thought and action of the host of competent workers in every land. The original germ theory has served its purpose well and descriptive bacteriology is being succeeded by the study of the contributing causes of bacterial diseases and of the factors which control the incidence and distribution of microorganisms. The doctrine of anaphylaxis, or increased and specific susceptibility to the action of chemical agents, promises to carry us far more deeply into the mysteries of disease than any previous contribution to pathology. The application of known medical principles to problems in sociology and in the prevention of chronic and hereditary diseases offers an immense field for the future activities of medicine. The great significance of the organs of internal secretion is being more clearly recognized and the revolutionary influence which this department of physiology seems likely to have upon the medicine of the future is in no sense belittled by the imperfections of our present knowledge. The science of nutrition seems to have entered upon an era of permanent progress, based upon the carefully attested data of the physiological chemist. The last decade has seen the science of eugenics take definite form, that science of the future which looks toward the day when every child born can be assured of a sound mind in a sound body. Experimental morphology and the studies of heredity warrant great hopes in this untrodden territory.

No one would prophesy which fields may prove most quickly productive, for all our problems are eventually solvable and time is of minor consequence before the steady advance of experimental science, that instrument to the power of which Pasteur saw no limitations. History justifies the fullest scope to the scientific imagination, for the miracles of yesterday are the commonplaces of today. It is a grave duty and a high privilege for every physician to see that his influence, in whatever capacity, tells for the realization of the ideals of medical science. For we look for the day when the cry of the innocent victim of disease, be he man or beast, shall be answered, and when the maladjustments of a vicious Nature shall be coerced and corrected by human intelligence.

The Blood Pressure in Diphtheria.—J. D. Rolleston found that 35.1 per cent. of 170 cases of diphtheria had a subnormal blood-pressure. He believes, however, that sphygmomanometry in diphtheria, as in other acute diseases, though of considerable theoretical interest, has little practical significance. Adrenalin therapy in diphtheria may favorably influence the other symptoms of suprarenal insufficiency without affecting the blood-pressure.—*British Journal of Children's Diseases.*

THE PRESERVATION OF HEALTH IN SCHOOL CHILDREN.*

By ROWLAND GODFREY FREEMAN, M.D.,

NEW YORK.

The infant under one year of age has received a great deal of careful study as to feeding and general hygiene, but the child over one year of age has been equally neglected; while the child at school usually receives attention only when he is sick, having few of the protective measures applied to him that are used to protect younger children.

Children of all ages acquire the contagious diseases to which they are exposed, until they have obtained an immunity. The children under one year of age are usually exposed only to colds and generally acquire these whenever thoroughly exposed. So-called colds, with their complications, comprise practically the only illness of well-cared-for infants, and from these they might have a complete immunity could the quarantine applied to other diseases be applied to the common cold.

Children living under good conditions do not usually suffer from any of the contagious diseases, which all children now have, until they enter school, after which measles, whooping cough, mumps, and chickenpox are acquired, and there seems to be no chance of ridding ourselves of these diseases unless some radical change may be made in the school management. Schools have been developed by educators largely from an educational standpoint, and physicians, although knowing their shortcomings and defects, have previously had little influence in modifying their methods.

On account of the neglect of children over one year of age, a fairly complete physical examination of every child beginning school life should be undertaken. When such examinations are regularly made surprising defects are found, often in the children of distinguished physicians, which have never before been suspected, especially defective vision and defective hearing. Neglected adenoids are almost never found in our good private schools. Such examinations, of course, involve a medical supervisor for every school, and this supervisor should have some authority and the cooperation of the school authorities.

The school day, while much better than formerly, is still usually poorly adapted to the younger children. A child of five should not have more than an hour a day at school, and this hour should be divided by periods of rest and exercise every ten minutes, for a child of this age has power of concentration for only the shortest period, and endurance for exercise for short periods only. They can run hard for a moment in play, but to walk a mile is fatiguing and injurious to them.

The duration of the school day may be gradually lengthened, as well as the periods of study, but at ten years of age the child should not be in school for more than four hours a day, and should have no home study, and this four hours should be interrupted by frequent recesses, every twenty minutes or half hour. These recesses should be taken out of doors, and every school in our large cities should be equipped with a roof playground for use during recess. Some of our most recent and expensive school buildings in New York have been built without roof gardens.

While our school day should be short in private

*Read at the twenty-third annual meeting of the American Pediatric Society, held at Lake Mohonk, June 2, 1911.

schools where facilities at home for the care of the children during the remainder of the day are good, I believe that our public schools should exercise supervision over the children as many hours of the day as possible, supervising their play as well as their study. In our large cities the influences about the public school children after school hours are demoralizing. The increased expense of this supervision should not be considered, as such expense would be amply compensated for by a later diminution in expense in the control of crime.

It is as true of children as it is of adults that it is not work but worry that breaks down the nervous system. We see in our clinics every spring conscientious school children, usually girls, who stand at the head of their classes and are studying day and night to keep up, and as a consequence developing anemia and chorea.

It is, therefore, very desirable that classes should be small so that the teacher may consider each child in her effort to obtain good results, and not push too hard the ambitious student or the stupid one who has difficulty in keeping up with the others.

The result of overwork was well demonstrated in two school girls who were brought to me for advice; the one, a good, conscientious student, who was editor of the school paper, stood high in her classes and was in many ways given extra work. She was pale, anemic, and poorly developed, while the next girl shown me, who had red cheeks, was fat and well developed, was brought on account of the utter discouragement of the school authorities, and was finally dropped from the school because she did not keep up with her classes. The gymnasium teacher said she could not coordinate properly. While perhaps stupid and awkward, she impressed me as being much better prepared for the duties of motherhood than the other girl.

A good teacher will get from a child the maximum amount of work consistent with good health, and all teachers should be instructed and should possess discretion and judgment on these points.

A simple method of determining accurately fatigue in school children is needed. After the work on the ergograph done under the supervision of Dr. Christopher on the Chicago school children it appeared that such a test was available which was accurate and satisfactory, but a very complete trial of this method by the author* convinced him that it was absolutely untrustworthy and did not indicate fatigue.

In an effort to eliminate the conveyance of contagious diseases in school, the separation of the children and the ventilation of the school room naturally play an important part. The effect of open, flowing out-of-door air on the health of all children is now well established, so that confinement of children in closed schoolrooms should, so far as possible, be eliminated.

The best schoolroom is the open air schoolroom now being used for some tuberculous children, but it is perhaps too much to hope that such schoolrooms may become common for healthy children at present. We should insist, however, on good ventilation in schoolrooms, and it has seemed to me that no system of forced ventilation has ever furnished such good air as open windows, and as the open windows interfere with systems of forced-air ventilation, most modern buildings are not well ventilated. While a free open window is suitable for most seasons of the year, during three or four winter months the intake of air may be modified by the use of cheesecloth screens. The idea that schoolrooms must be kept at a temperature of seventy or more must give way, for the children would be far better off, if properly clothed, with a temperature of fifty or sixty, in a room that is well ventilated.

*"Fatigue in School Children as Tested by the Ergograph," Rowland G. Freeman, *American Journal of the Medical Sciences*, November, 1908.

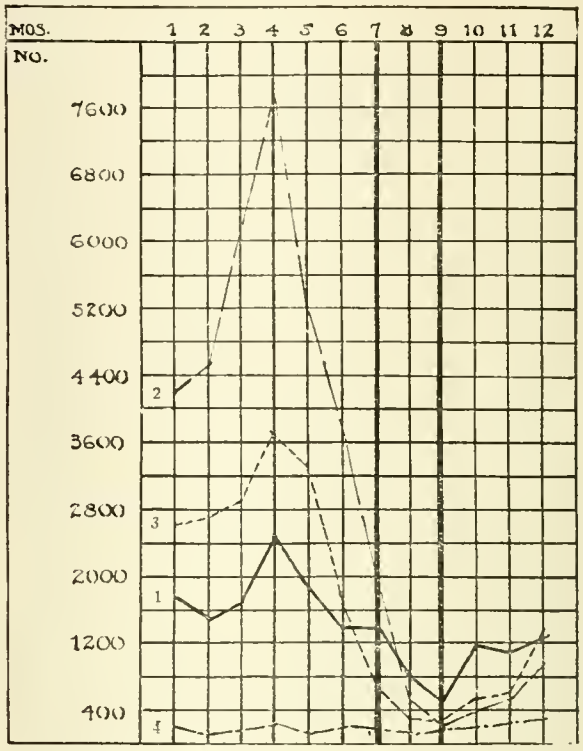

Chart I.—Monthly Morbidity in New York in 1910 from diphtheria 1, measles 2, scarlet fever 3, and whooping cough 4.

The important question of the feeding of school children I will only mention. It is a self-evident fact that no city that compels attendance at school should compel children to do this work who are insufficiently fed, and that our city authorities should supply one nourishing meal in any case where there is a question of the child's obtaining sufficient food at home.

In the private boarding schools the opposite tendency is to be counteracted, that of allowing children to eat too much and often a food that is difficult of digestion. This should be easily remedied by proper medical oversight.

The fact that the schools are the chief means of communicating contagious diseases to children is well demonstrated in certain charts which I have prepared.

Chart I shows the morbidity from diphtheria, scarlet fever, measles, and whooping cough in New York in 1910, and demonstrates well how these diseases begin to spread as soon as school opens in the autumn, continue to be more frequent during the school year, until the mild weather comes and the windows are thrown open; then there is a slight diminution, while so soon as the schools are closed there is a very slight incidence of these diseases. It is interesting to note on this chart that the incidence of whooping cough has little relation to the school year. Just why this is so it is difficult to say, although it is a fairly chronic long continued disease, probably badly reported, while the deaths from it are usually due to some complication and

are probably reported under the name of the complication. Chart II, which shows the average monthly mortality for five successive years, shows the same school year incidence.

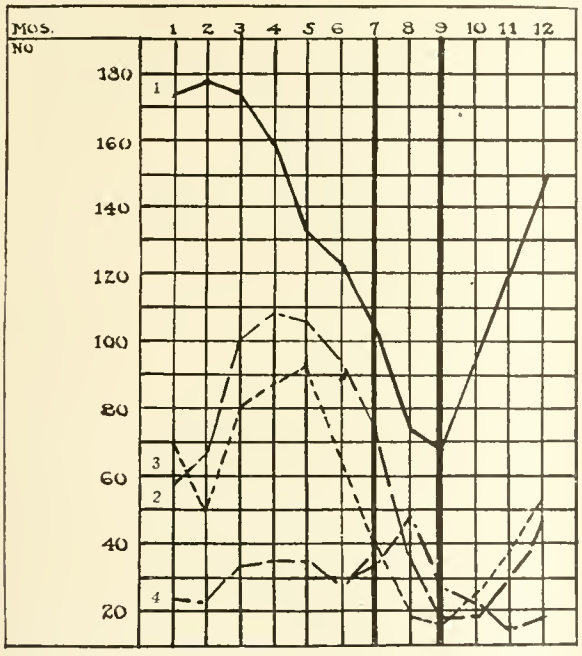

Chart II.—Average monthly morbidity in New York, 1903-1908, from diphtheria 1, measles 2, scarlet fever 3, and whooping cough 4.

I do not claim that this great morbidity and mortality of measles, scarlet fever, and diphtheria during the school year are due to the schools alone, but I do believe they are the greatest factor, and additional evidence in favor of this statement is obtained by studying the Chart III, of mortality for five years in London. The school year ends a month later than ours, August 1, and the term commences two weeks later. It is noticeable that the bottom of these curves occurs in this period. This English chart shows that diphtheria and scarlet fever remain much lower and do not increase so materially in the school year.

The elimination of this conveyance by schools of diseases can be very materially modified by the intelligent application of two very simple regulations.

The diseases which are most commonly conveyed at school and which interfere most of all with the attendance and well-being of the children include the nose and throat infections known as colds, measles, German measles, scarlet fever, whooping cough, and diphtheria. It is evident that all of these give the first tangible evidence of their presence to the laity by coughing, sneezing, nasal discharge, or the symptoms of a sore throat, all of which are commonly known as a cold. So that if every child with a cold is excluded from school, the likelihood of schools being the means of conveying any of these diseases is immediately minimized. The enforcement of this rule against colds is not difficult of application if the parents understand the existence and advisability of such a rule before their own children become afflicted. The neglect of the enforcement of this may have serious results, as was the case in a small kindergarten where the children of a physician were continually coughing and the teacher suspected whooping cough. The physician insisted that it was not whooping cough and the woman in charge of the class deferred to his greater authority, with the result that before the end of the school year all the children in the kindergarten had whooping cough, and this unfortunate woman was left without any class.

The enforcement of this rule against the presence

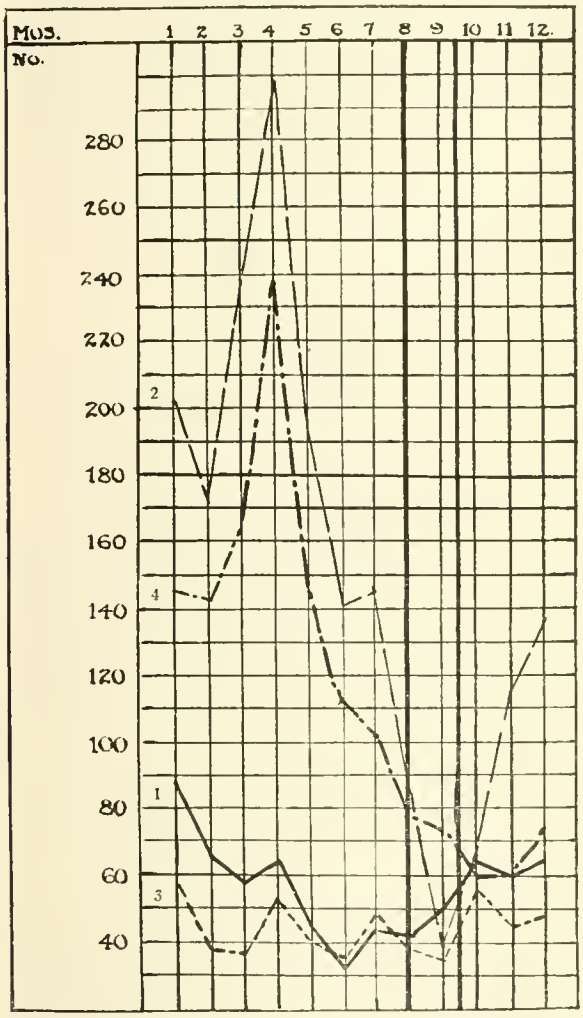

Chart III.—Average Monthly Morbidity in London, 1905-1910, from diphtheria 1, measles 2, scarlet fever 3, and whooping cough 4.

of any child in school with a cold seems to be most important in all schools in order to keep the children healthy.

The second rule to which I referred is the exclusion from school during the period when the disease is apt to develop of all children who have been exposed by children taken sick at school. This means usually the members of the child's class and generally involves an exclusion of from one to two weeks.

The efficiency of the enforcement of such rules is well shown in the incidence of contagious diseases in a private school in New York having 200 children. During the year 1908 to 1909 there were 9 cases of measles, 3 of mumps, 1 of whooping cough, and 1 of chickenpox, 14 cases altogether. In the year 1909 to 1910 there were 4 cases of chickenpox, 7 cases of measles, and one of whooping cough, and only 4 of these 12 cases were contracted at the school from a previous case; while during the past year 2 cases of chickenpox, 1 of measles, 5 of whooping cough, and 5 of scarlet fever occurred; 12 cases of contagious diseases, and I believe none of these were contracted at the school.

For the efficient application of this latter rule the cooperation of the parents must be obtained,

and the efficiency of such rules may be nullified by the absence of such cooperation. This was well shown recently in a case where one child was excluded from school on account of having been exposed to a contagious disease, and during the period of exclusion attended a party where most of the members of her school class were present, and this resulted in these other children also being excluded.

From the results reported above it is evident that school authorities should, as a rule, be held responsible for epidemics that are allowed to spread in their schools.

In conclusion I would summarize the following essentials for the preservation of good health in school children:

Short school hours.

Frequent recesses.

Open air or well ventilated and cool schoolrooms.

Roof playgrounds in cities.

Individual study of backward or feeble children.

For public school children a supervision of play as well as of study.

The proper feeding of school children.

A medical supervisor who shall have control of the preservation of health in the school children.

The exclusion from school of all children with colds, as well as those suffering from other contagious diseases.

The dismissal from school during the period of incubation of all children who have been exposed to contagious diseases.

211 West Fifty-seventh Street.

THE CARE OF THE CRIPPLED AND RACHITIC IN ITALY.*

By DOUGLAS C. McMURTRIE,

NEW YORK.

Even the most casual observer comes away from Italy with an impression that the problem of caring for cripples must there be of great importance. On all sides one sees cripples in abundance and most of them use their deformity to work on the sympathies of passers-by and promote their own success as mendicants. The universality of the profession of begging for cripples has rather complicated the problem, in that it renders the deformity a definite economic asset and thus largely vitiates the desire for cure. The provision and methods of care for cripples are thus rendered of particular interest. In early times there was nothing whatever done to improve their lot and they shared, in common with the cripples of other European countries, the scorn and scoffing of the community. Their only possible occupations were those of jester or beggar.

The first interest in ameliorating their condition was shown in 1839 with the opening of the Orthopedic Institute, which was founded at the instance of Professor Ferdinando Carbonai. In a general way it was modeled after the Pravaz Institution at Lyons, France, with a capacity for but thirty patients at the start. It was later considerably enlarged. The orthopedic treatment was rather primitive but thoroughly constructive in character, and much of the apparatus used was designed and made at the Institute. Corrective gymnastics and hydrotherapy were much in favor and the value of hygiene and exercise in the open air was appreciated. At first only pay patients, and those too of considerable wealth, were received, but later through the addition of an orthopedic clinic, which was donated by the Tuscan government, it became possible to extend treatment to cripples of the poorer classes. The patients were given elementary education to a limited extent so as not to tire them. One year after the death of Professor Carbonai, in 1888, the institution was closed.

In Turin there was a regulation excluding rachitic children from the public schools, and the result was that children so afflicted spent all their time on the streets, received no education, and so could hardly be trained for any trade. Realizing the situation, Count Riccardi di Netro, who was then supervisor of public instruction in the city of Turin, started a class for rachitic boys in 1872. This first class was for children between four and seven years of age, and there were selected as pupils children who had passed the period of softening of the bones, and whose frame had hardened. The children were given a reasonably good schooling and received medical and surgical treatment from Professor Gamba, who installed the equipment for this purpose.

The success of this experiment brought about the foundation of a philanthropic organization to stimulate the establishment of other schools of a similar type. In a short time this organization was able to open four new schools, located in the poorer districts of the city of Turin. From Professor Gamba's report to the Royal Medical Association in Turin we learn that during the first eleven years of the organization's existence 1,600 rachitic children were received. Of this number 850 were cured or so much improved that they were either admitted to the public schools or were able to take up a trade. By 1892, 3,286 rachitic children, in all, had been cared for. A large proportion had been rendered independent—so trained that they were able to earn their own living in the normal ways. The organization furnished special education to those who were still dependent, instructing them in the trade best adapted to their intelligence, physical ability, and inclination.

In 1886 there was founded the Institution for Rachitics in conjunction with the schools. To this were admitted those cripples who needed active surgical or medical treatment which they could not receive in the schools. From fifty to a hundred children could be received yearly, half of them without charge. A complete orthopedic equipment was installed. In the educational department of this institution there are three large schoolrooms, a gymnasium, a large recreation room, and a garden. During 1909 the school attendance was 169, of which 101 were boys and 68 girls.* The emphasis is placed on work with young children, as will be seen in the age distribution: 58 between three and four years, 56 between four and five, and 55 over five years of age. Practically all are under seven.

The children are brought to school every morning in two omnibuses, each with a capacity of fifty children. Stops are made to pick up the children at eight specific places in the city. The children stay in school from 8:30 A. M. to 4:30 P. M. in winter, and from 8 A. M. to 5 P. M. in summer. New pupils are received October 1 at the end of the September holidays. The children receive two meals consist-

*In the preparation of this article I wish gratefully to acknowledge the assistance of Miss Dorothy Jacoby. For a large amount of the material I am indebted to an article by Professor A. Codivilla, *Zeitschrift für Krüppelfürsorge*, I, pp. 294-209, 257-277.

*Report of Istituto pei Rachitici, Regina Maria Adelaide, Turin, 1910, p. 17.

ing of vegetables, meat, bread, milk, and wine. They are also given cod liver oil or some other tonic.

The children are required to take a weekly bath; a specially trained teacher instructs them and sees that the proper gymnastic exercises are performed under the direction of the physician. The physician visits the various sections of the school daily. Every three months he renders a report concerning the condition of each child: change of weight, height, and general health. There are two summer homes to which the children are sent during the long holiday so that they may get the full benefit of the fresh air. At the end of August it is decided which children are to return the following year and which, because of their age, improvement, cure, or impossibility of cure, are to be dismissed.

Children usually attend the school for three years. Special cases are transferred for necessary surgical care to the hospital, which is another department of the institution. In the hospital section children between the ages of three and fifteen years are received for orthopedic treatment. The poor of the city are admitted free; others pay from $4 to $16 a month. This department of the institution, which originally had but four beds, now accommodates 45 patients. The department for corrective gymnastics receives children between the ages of three and fifteen. There is also a dispensary or clinic in which 602 patients were treated during 1909.

Considered as a whole this institution at Turin has an excellent equipment, the various departments being all located within an enclosure. A lively interest in the work has been aroused among the citizens of Turin; two additions have already been made and a third is projected. The address is: Istituto pei Rachitici, Corso Firenze, N. 43.

The example set by the city of Turin was followed by other Italian cities. In Milan the School for Rachitics was opened in 1875. The school was founded along the same lines as the Turin institution largely through the instrumentality of Dr. G. Pini. According to Dr. Pini's report, the purpose of the institution was to "take charge of rachitic children for several hours of the day, to give them orthopedic treatment, and instruct them in such branches of learning as would be of use to them in after years."

The first financial support for the building of an orthopedic hospital was given by a bequest of Marquis Visconti, as early as 1850. One can, therefore, say that the idea of such an institution existed in Milan prior to this date. A dispensary was soon added to the modestly equipped school, and it was hoped that by fundamental measures of care the spread of rachitis might be checked. From 1875 to 1883, 3276 patients were treated. Some wards were added so as to allow the patients to stay at the institution a longer time instead of returning to unhygienic homes. Thus the "Istituto pei Rachitici" made up of school, dispensary, and hospital was formed. The purpose of this charitable undertaking is set forth in the constitution, an extract from which follows:

Art. I. The aim of the Institution for Rachitics, founded in 1874 in Milan by Dr. Gaetano Pini, is to prevent the development of rachitis and to give treatment to those children in Milan who have contracted it.

Art. II. The following means, prophylactic to the spread of rachitis, are to be used: (*a*) Giving mothers instruction in hygienic treatment. (*b*) Prophylactic supervision of sucklings and weaklings. (*c*) Giving mothers instruction regarding the better nourishment of children. (*d*) All other means of combating the causes of rachitis.

Art. III. Attempts are made to further the mental and bodily development of rachitic children: (*a*) Through the school. (*b*) Through corrective gymnastics. (*c*) Through all other methods of rational pedagogy.

Art. IV. The fulfilment of these aims as far as possible with the aid of schools and hospitals which are at the disposal of the institute and commensurate with its finances.

The school, dispensary, and general hospital are now located in the main building of the institution. Though the building was erected in 1881 it is modern in all of its equipment. The school accommodates 100 children and there are 36 beds in the hospital. There have been recently added an operating room, a gymnasium, and a department of hydrotherapy. There was also erected an isolation ward.

In the Milan institution there are admitted children who show no sign of consolidation of the bones. Patients eighteen months old, and some even younger, are therefore received. So in Milan not only the treatment but also the prevention of rachitic deformities was considered. The number of beds is now 70 and accommodation for 150 pupils was added at the school. At the school only the worst cases are admitted and children between the ages of two and five are given the preference. Particular attention is paid to the prophylaxis of rachitic deformity.

The Industrial Home for the Crippled and Maimed has lately become associated with the Institute for Rachitics.

Following the example of Turin and Milan, Genoa opened a school for rachitics in 1878. The school had small quarters until 1883, when it moved to a place occupied by an old convent, where there was sufficient room for a dispensary, hospital, and school. At the institution the patients had the benefit of sea baths in the summer. After 1899 the institution inaugurated climatic treatment, and a large number of the patients were sent to the mountains for a part of the year. In the school from 50 to 100 children, and in the hospital from 20 to 30 children, are admitted yearly. Recently the institution has been greatly improved. The school and dispensary have remained in the heart of the city while the hospital department was moved to the outskirts. It commands a magnificent view of the Bay of Genoa. This new branch embraces three buildings of the best modern type.

The next city to make provision for cripples was Mantua, where a School for Rachitics was established in 1879. Until 1899 the children received treatment either at the dispensary or in the schoolroom, but there was no hospital provision. The original plans, however, were completed in 1899 and facilities for surgical treatment were added. The institution now compares favorably with those in the larger Italian cities. During the past few years 200 children have been provided for in the wards and 250 children have attended the school.

In Cremona the Institution for Rachitics was opened in 1881. Later it was consolidated with the Children's Hospital, "Ospedale dei Bambini"; was rebuilt in 1902 and is now an excellent orthopedic institution.

In Bergamo the Institution for Rachitics was founded at the instigation of Dr. Rota, its present superintendent. In general construction and equipment it is patterned after the one at Milan. At first the dispensary, the ambulance service, and school were put in commission. Later, in 1887, the hospital department was added. In the first 22 years of its existence 1,445 rachitics were treated and given instruction, 1,597 operations were performed. The institution has recently undergone alteration and is now splendidly equipped. The location is unsurpassed, being on a hill-top.

In Brescia the establishment of an institution for rachitic patients was projected as early as 1882, but on account of financial disability it was not opened until 1894. It comprises the following departments: (*a*) The school children from 3 to 7 are admitted. They attend the school during the day and return to their homes in the evening. They take breakfast and a midday dinner at the school and receive, besides, general treatment, baths, douches, corrective gymnastics, massage, and electrotherapeutic treatment. (*b*) Wards: in which children are examined, braces, apparatus, etc., are fitted. (*c*) Dispensary: this contains 16 beds, operating rooms, etc. Children, whether or not from the schools are admitted for immediate treatment.

The institution effects splendid results, about one-third of the children being dismissed yearly as cured. They then enter the regular public schools. From 140 to 160 children are received yearly, 50 of whom are cared in the wards.

In Verona, Venice, Padua, and Modena there are schools or educational institutions for rachitics, having dispensaries but being without hospital facilities. On account of lack of funds, but a small number of patients are cared for. There is a seashore home for the rachitics of Padua and a mountain sanatorium for those of Modena.

For about four years, 1897-1901, a school for rachitics was connected with the Rizzoli Orthopedic Institute at Bologna. But after this period the school could not be continued on account of the necessity of using the funds devoted to it for the support of other lines of work. The success of the school during its period of operation renders its reopening highly desirable. Rachitic children under three years of age were not admitted to the institution. The dispensary was located in the city and the children were examined there before admission to the school, which was outside the city, splendidly located on an elevation. An omnibus called for the children in the mornings and returned them to their homes in the evenings. An attendant from the institute always accompanied the children. At the age of eight the children were dismissed, those who needed acute treatment being retained later. The majority, however, came afterwards to the outpatient department for treatment. Children with other deformities were in exceptional instances admitted to the school. The school was open for eleven months of the year. During the other month the children were sent to the seashore. The average daily attendance was about 60 per cent. of the total enrollment.

In the school building there were the following rooms: a dressing room, a school room for 80 to 90 children, a resting and play room, a massage room in which 5 children could be treated at a time and in which measurements were taken and examinations made, a bathroom with 5 baths, a large dining hall, washrooms for the employees and for the children. Adjoining these school quarters were a large gymnasium with Zander apparatus and other equipment, operating rooms, large protected and heated halls, and extensive gardens.

Up to the present there have been considered only those institutions for the education and care of rachitic children. Some of the institutions described would be better designated as orthopedic—particularly the one at Milan. They still retain the original appellations, however, as institutions for rachitics in order to make their origin clear. On the other hand, there were formed some institutions with the original purpose of treating all types of deformity.

The most important and widely known institution of this type in Italy is the "Istituto Ortopedico Rizzoli," at Bologna, reference to the educational work of which has already been made. It was named after the illustrious Bolognese surgeon, Francesco Rizzoli, who in 1880 bequeathed all his wealth for the foundation and support of this institution. According to the desire of the benefactor it was to be started in the Convent of the Olivetes, which had been purchased for the purpose by Professor Rizzoli. The institution was to be conducted with three purposes in view: the advancement of science, the good of humanity, and the "good and honor of the fatherland." Therefore, the benefactor selected this historic site for the fulfilment of his far-reaching plan, not only because of its adaptability to the purpose, but also because of esthetic considerations.

Nearly 15 years were spent and $280,000 were expended to restore, remodel, and equip the building. Owing to the natural advantages of the building, at the present time it is excellently suited for the work. Also the rooms are much more generous in size than would have been the case in a new building.

One hundred and fifty beds are provided. Much of the building is given over to large halls in which the patients are able to take all their exercise. One of the largest rooms in Italy, 170 yards long, is on the first floor, and from this one can get some conception of the scale of construction. On the ground floor is a large court enclosed with glass and heated in winter. In other parts of the building are washrooms, a gymnasium, rooms for various orthopedic treatments, laboratories, the library, and the museum.

The operating department is large and contains rooms for the use of orthopedic apparatus, as well as rooms in which patients are examined. The other rooms—the dining halls for patients of various kinds, living rooms, reading rooms, the library, the music room, the billiard room, and the skating rink—should also be mentioned.

The beautiful and healthful location of the institution has already been mentioned. Situated on a hill to the south of Bologna, it has a remarkable view over the city and the surrounding fertile country. There are beautiful shady gardens for the patients on the grounds.

The institution has a dispensary in the city, where examinations are made and treatments given, and surgical operations performed. It possesses excellent facilities for treatment of all kinds.

The poor people of the Province of Bologna are treated free of charge; one-third of the 150 patients are non-paying; two-thirds are paying patients. A large portion of the latter class pay only a part of

their expenses. The running expenses are paid partly by the interest from Professor Rizzoli's bequest, partly from the money received from the paying patients. The expenses, which in the first years of the institution (1897-1899) varied from $8,000 to $12,000, amounted last year to $34,000. During the eleven years since the institution was started 3,600 patients, mostly from the several Italian provinces (though some were foreigners), have been treated.

The prize donated by King Humbert I should be mentioned. It is an international prize of $700 and is awarded every five years for the greatest work on discovery toward the advance of orthopedics. In 1905 the prize was awarded to Professor Oskar Vulpius for his work in transplantation of tendons. The physicians of the Istituto Ortopedico Rizzoli are not allowed to compete for the prize. The members of the committee for awarding the prize are chosen from the Italian medical faculties.

The Orthopedic Institute in Naples was endowed by the Countess Ravaschieri in 1900. It consists of: (1) The dispensary. Here cripples from all provinces are examined. Swedish gymnastic exercises and massage treatment are given. Small operations are performed, plaster bandages are applied, etc. (2) The free wards, which consist of four large rooms, for men, women, boys and girls. (3) On the second floor—a second-class division for those patients who are able to pay a small sum. (4) A private division for those who are able to pay (first class).

Treatment is given in the following departments: (1) Surgical—Orthopedic Department. (2) The Kinesitherapeutic division—for 350 patients. It contains apparatus for active and passive movements. It also contains massage and dressing rooms. (3) The hydrotherapeutic division. This consists of two bath rooms, dressing rooms and showers of the different systems. (4) An electrotherapeutic division with all apparatus for electrotherapy, static, galvanic, and faradic electricity, hydroelectric and light baths. (5) Orthopedic work shop. (6) Scientific laboratories for clinical and microscopic analyses, for radiographic and photographic plates.

In July, 1906, a beautiful home at the sea was added to the Istituto Ortopedico of Naples—in Bagioli. It is a roomy and airy home by the sea. The building is surrounded by a garden. In this garden there is a chapel and a room for the mothers who visit the children. On the ground floor are the boys' dormitories, an examination room, dressing room for the children, etc. On the first floor are dormitories for girls, the school room, the Sisters' rooms, and a large parlor.

Children apply for admittance to the Orthopedic Institute at the dispensary. Emphasis is laid upon hygiene, healthy diet, sea, sand, sun, and air baths.

Sea and Mountain Homes.—A long time ago sea and mountain homes were started for the treatment of rachitis and other illness which cause deformities. Children suffering from rachitis, from noncontagious forms of tuberculosis, scrofula, anemia, or general debility were sent to the mountains or to the sea for several months in summer. These prophylactic measures are now part of the treatment for deformities. The existing colonies among the Alps have been modeled after those in Germany and Switzerland.

Seashore homes were originated in Italy and were later adopted by other countries. The first home at the seashore was founded at the instigation of Dr. Barellai, in 1853. At first only a small number of children were sent to the sea. No special provision was made for them. Later, however, a home with room for 100 children was built in Viareggio; after this other homes were built in the Riviera and on the Adriatic.

At present there are a great many homes of this kind, and each Province in Italy has its own institute for children suffering from rachitis, tuberculosis of the bones, etc. There is no question about the benefits derived from this treatment. It is greatly to be desired, however, that children suffering from the more serious cases should spend a longer time in the country.

All the seashore homes, or at least a part of them, should be turned into hospitals (sanatoriums) and kept open all the year. A few attempts in this direction have already been made. This arrangement has been made in the seashore home at Palermo, which was started through the efforts of Surgeon Enrico Albanese. At first, in 1874, the institute was a regular seashore home. Later, however, it developed into a hospital for diseases of children. Special departments for orthopedic surgery and cure by other methods were formed so that for three months of the year it was a seashore home and the remaining time it was a regular hospital. In 1880, in this new capacity, the hospital admitted 55 children. From that time on it was enlarged, and at present it is being greatly improved. The best possible results are being obtained for rachitics and cripples in this institution through its surgical, orthopedic, and kinesitherapeutic treatment and its sea, sand, and sun baths.

Schools and Industrial Homes for Cripples.—In the erection of schools for rachitics in Italy a great step was made toward warding off the physical and mental deterioration of cripples. The schools also provide them with independent means of support.

The excellent example set by Germany, Denmark, etc., in their successful professional schools for cripples has unfortunately not been followed by Italy. The need of such schools for professional training was appreciated from the start by the founders of the schools for rachitics, and this need was partly met in that the schools for rachitics prepared their pupils for the occupations which were most adapted to their tendencies, talent, and strength.

In 1877 the Congress of the Italian Medical Society and the Societies for the Improvement of the Condition of Rachitics made the following resolution: "The Congress demands that a professional school be erected for those rachitic children whose deformities are incurable. In these schools the children should be taught the arts and crafts which can be practised without injury to the bones, and especially to the spine." This demand, however, appealed little either to the people as a whole or to private individuals.

Italy, which had done so much for the treatment of cripples along this line and had acted as an example to other countries, was far behind when it came to bettering the social welfare of the cripple.

An urgent appeal was made by Professor Codivilla, on December 3, 1905, on the occasion when the prize of Humbert I was awarded. He asked for the foundation of institutes like those existing in Germany, Austria, Denmark, Sweden, and Russia. In these institutions instruction should be given to the cripples in proportion to their physical

strength and intelligence. "Just as orthopedic treatment improves the physical condition of children so their mental ability will be fully developed by wisely planned teaching, and the learning of a trade or occupation, which is adapted to the individual need."

At this time, too, Professor Galeazzi made out a report for the Fourth International Congress on Public and Private Institutions Which Care for the Sick, held at Milan (May 23-27, 1906). In this report Professor Galeazzi, pointing out the success of other countries in the social betterment of the deformed, appeals to the State, the people, the charitable institutions, and the insurance companies to lend their moral and material support to the erection of schools and industrial homes for cripples. This time the appeal was not in vain. The first industrial home for rachitics was endowed by the generosity of Mr. Carmine, President of the Institute for Rachitics, in Milan. This home will be opened in connection with the Institute for Rachitics. The idea of affiliating the school with the institute is a happy one, the pupils thus deriving double benefits.

The new school will be an industrial school only. Crippled, paralyzed, or maimed people will be admitted to the school only if their physical or mental strength will be improved by attendance. All pupils, excepting those who wish to become teachers, will be dismissed from the school upon completion of their training. Complete provision will have been made for cripples when the Institution "Ottolenghi Finzi," near Milan, for entirely incapacitated cripples, is finished. After leaving the school cripples of the following classes will be admitted to this institution: (*a*) Those neither able to find employment, or to return to their homes; (*b*) Those incapacitated through accident or illness. Here they will do such work as they are able to. Some of the cripples will be taught farming and agriculture; for others work rooms will be fitted out.

The women in the school connected with the Institute for Rachitics will learn washing, ironing, and sewing, tailoring, finishing of orthopedic braces, and leather work. The men will also work in the tailoring department and will help make orthopedic shoes and the miscellaneous parts of orthopedic apparatus.

The institute should show splendid results. It is to be hoped that all the other Italian cities will soon follow the example of Milan and that the State will also aid in the development of similar work.

It is evident that there has been taken in Italy considerable interest in the welfare of the cripple and there have been inaugurated and developed many methods of great suggestive value. It will be seen that the emphasis has almost always been on the aspect of physical or orthopedic care. In this connection, however, there is one point which should be very carefully observed; that is, that the treatment is given at a very early age before the time when the average child can attend school, and by taking the deformities in hand a large proportion of them can be cured and others prevented from becoming serious. The provision for the care of infantile deformities is extensive and adequate. An obvious weakness of the situation, however, is the extreme emphasis that has been placed on rachitic deformities which are known to constitute but a part of the orthopedic problem. For other classes of cripples the system is far less adequate.

In the plan of having day schools and dispensary treatment for crippled children Italy has developed a system which is also followed in England and the United States. In Great Britain there is a very extensive system of day schools and clinics for cripples, which are authorized by law and receive partial support from the National Education Fund. In the United States, New York City and Chicago have instituted special classes to which deformed pupils are transported each day, while they still continue living at home.

After all, however, perhaps the best lesson to be learned from the work done for cripples in Italy is that prevention as well as relief and cure should be, and must be considered as, an important factor in dealing with the problem of human deformity.

D'ARSONVALIZATION IN THE TREATMENT OF HYPERTENSION AND ARTERIOSCLEROSIS.

By WILLIAM BENHAM SNOW, M.D.,

NEW YORK.

The term d'Arsonvalization is applied to the employment of the arrangement for administration of the high-frequency current by the methods devised by Prof. d'Arsonval of Paris. Two arrangements comprise this method of administration, both consisting of solenoids or wire spirals connecting the outer coats of two condensers, the inner coats of which are connected to an electrical source of high potential or high voltage. In one case the current is administered by the *autocondensation* method, employing the d'Arsonval current as indicated in Fig. 1. By this arrangement the patient is seated upon a couch, upon which is placed a cushion of nonconducting material, approximately three inches in thickness, such as felt, or silk or cotton waste, having beneath it a strip of metal extending within two or three inches of either end of the cushion, and five or six inches narrower than the cushion. One end of the d'Arsonval solenoid is connected directly to the metal condenser beneath the cushion, and connected to the other end of the d'Arsonval

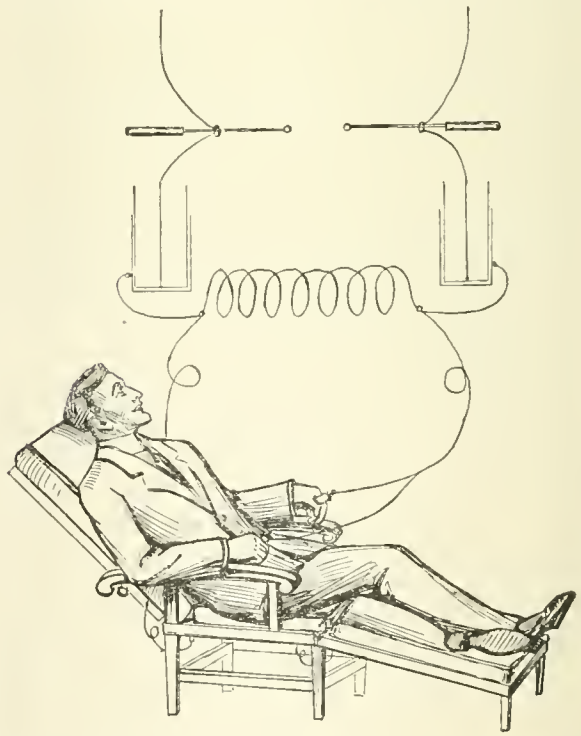

Fig. 1.—The Autocondensation Method.

solenoid is a bifurcated cord provided with two electrodes to be held in the hands of the patient, or this may be substituted by a single cord having at one end a longer metal handle upon which the two hands may be placed. The hands of the patient should either rest upon a cushion upon the lap, or upon the two arms of the autocondensation couch to prevent sparking through the clothing. By the other arrangement, known as *autoconduction,* a large solenoid is placed either horizontally or vertically, and is large enough to envelop the patient from either end. This large solenoid is connected to the outer coatings of the Leyden jars, as shown in Fig. 2.

For the administration of these currents, a large static machine, or Ruhmkorff coil, or other high-potential transformer, constitutes the source of electrical energy, in connection with a resonator consisting of two Leyden jars, a spark-gap, and solenoid connected in series. The spark discharging at

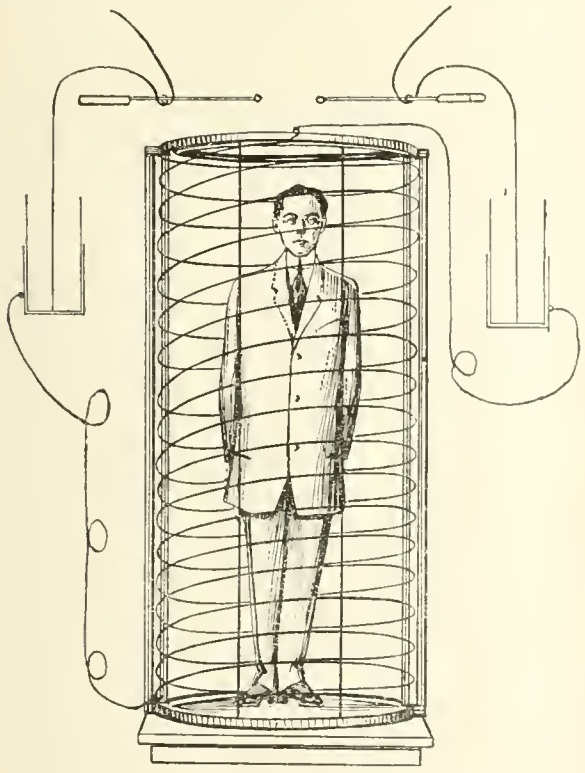

Fig. 2.—The Autoconduction Method.

the spark-gap induces synchronous discharges from the outer coatings which set up oscillations in the solenoid connecting the outer coating to the two Leyden jars. By connecting cords to the terminals of the solenoid, the oscillatory current thus induced is carried from the two terminals to the object or capacity placed in circuit, constituting the d'Arsonval current as previously described. A physician already provided with an *x*-ray coil, high-potential transformer, or large static machine is in a position by the addition to his outfit of a resonator, hot-wire meter, and autocondensation couch, or d'Arsonval solenoid, to employ d'Arsonvalization for therapeutic purposes.

D'Arsonval in his experiments nearly twenty years ago demonstrated the effect of this current upon the arterial tension, and for a considerable time physicians have employed it for that purpose with varying degrees of success, depending upon their knowledge of the technique. It is not however, until comparatively recent times, that the value and import of d'Arsonvalization in the treatment of hypertension and arteriosclerosis has begun to be recognized as a measure of importance in therapeutics. Current literature and discussion indicate that the profession at large is not as yet cognizant of the great value of the systematic employment of this method in the management of cardiovascular diseases. The writer has employed the method in a large number of cases during recent years; and is impressed with its value and importance. There are certain facts concerning the physiological effects of this current which indicate its employment in various conditions.

(1) When administered either by the autocondensation or autoconduction method, the blood pressure promptly falls from 10 to 70 mm. in all except the most advanced cases of arteriosclerosis. (2) That the action of this current is upon the musculature of the arteries and not due to depression of the cardia is demonstrated in the daily treatment of persons of advanced age, in whom the sclerosis is so extensive that it is not possible to affect the lumen of the vessels, and still the blood pressure does not fall as it certainly would if the heart was depressed. (3) The administration of the current to aged people in whom there is no fall of blood pressure, after daily treatment for periods of months, is followed by an improvement in general health, attributable to its effects upon general metabolism. (4) Undoubtedly in all cases in which this current is administered this same effect upon metabolism plays an important rôle in the therapeutics of d'Arsonvalization. (5) In cardiovascular conditions, in which the heart is laboring against other impediments, as mitral or aortic insufficiency or both, associated with hypertension, the lowering of blood pressure gives indicated relief to the overtaxed cardia. It is for these reasons that d'Arsonvalization fills a most valuable rôle in the therapeutics of hypertension and arteriosclerosis.

It has been stated by some recent writers that hypertension is as a rule compensatory. This ex experience teaches to be an error, except in cases of parenchymatous nephritis, cirrhosis of the liver, or whenever incidental resistance other than hypertension is present in the path of the circulation. It is a serious error to assume that hypertension is, as a rule, compensatory; because when it is possible to release the heart from the extra labor of a contracted arterial hypertension the arteries are at the same time released from a condition which otherwise seriously interferes with their metabolism and nutrition. It is probable, if not certain, that by so doing a process of degeneration is halted which would finally terminate in arteriosclerosis. It has been stated by some authors that rest is indicated in cases of hypertension. True, it may be, when the arterial blood pressure approximates 200 to 230 mm. when an extra exertion or excitement might occasion the rupture of sclerotic arteries. If, however, by feasible means it is possible, as it is by the autocondensation method, to reduce these high pressures to a point ranging from 140 to 160 mm., there is nothing that contributes more than exercise except a proper diet to the preservation of a standard pressure condition. The writer's experience with many cases having extremely high arterial tension has demonstrated that in patients in whom the blood pressure can be lowered readily to from 130 to 140 mm., and all animal food, including fish and fowl, is eliminated, together with a reduction of the quantity of food and systematic

exercise, it is possible to maintain a standard of low blood pressure by these means alone. This can be effected in all cases except cases of advanced arteriosclerosis.

Finding no classification for cases of arteriosclerosis and hypertension in works upon the subject, the writer, in a paper read in 1908,* adopted the following classification based upon the response to d'Arsonvalization and upon conditions associated with cardiovascular phenomena. In this classification are included seven types of cases or conditions:

Class I consists usually of aged and feeble persons in whom the blood pressure has undoubtedly been high, but owing to an advanced condition of arteriosclerosis, with lowered nutrition and weakened heart force, as commonly associated with valvular lesions, or with cases of dilatation without hypertrophy, the condition is one of failing compensation. When the sphygmomanometer in any of these cases indicates an arterial tension above normal, there is nothing that will give greater relief than d'Arsonvalization if the pressure falls following an administration, because the overworked and feeble heart is thus relieved of the extra labor necessary to overcome arterial resistance, together with an added beneficial effect of the current upon general metabolism, which otherwise improves the general health and nutrition of the patient.

Class II comprises cases of advanced general arteriosclerosis as occasionally found in the aged, in whom the arterial changes are such that the musculature does not respond as in other cases to d'Arsonvalization, and the pressure does not fall. In these cases it is probable that all the arteries which treatment relaxes in other cases are in a condition of arteriosclerosis. These cases, however, are benefited, as previously stated, by daily or otherwise frequent administration of d'Arsonvalization; and when kept at rest, on simple diet and with very moderate exercise, often live for several years in this condition without suffering either from apolexy or Bright's disease, though the tension may remain very high for years.

Class III comprises cases of arteriosclerosis in those of advanced age, and occasionally in ages as early as 50 to 60 years, which respond slowly to d'Arsonvalization without evidence of cardiac depression, but finally under persistent treatment are reduced and maintained at a safe degree of hypertension with corresponding improvement in general health. In these cases in which the reading at the outset may be 200 to 260 mm., as indicated by the sphygmomanometer, the tension may be scaled down in the course of a month or six weeks by daily or alternate day treatment to 140 or 160 mm., at which it may be maintained by strict regulation of diet, exercise, and occasional treatment. These are usually cases of advanced arteriosclerosis with cardiac hypertrophy, but clinical observations indicate that, when under treatment by d'Arsonvalization, a marked vasomotor relaxation takes place, probably of blood-vessels of uniform lumen, which are not sclerosed. The general improvement of these cases and the fact that after several years of treatment there are no signs of failing compensation, but on the contrary a general improvement in the health of the patient, indicate its uniform employment as a judicious measure. By such means the labors of the heart are lessened, and apoplexy and nephritis delayed. Likewise in cases of angina pectoris, with coronary sclerosis, when the nutrition of the heart is thus lessened, the lowering of blood pressure, with diminished labor of the heart, will to a remarkable degree relieve the painful symptoms of angina, thereby lengthening the life of the patient.

Class IV includes cases of advanced arteriosclerosis usually in mature adults, ranging from 35 to 70 years of age, in which the tension may have scaled from 150 to 200 mm. In these cases the administration of d'Arsonvalization by the autocondensation method will produce a marked fall in arterial tension, usually 15 or 20 mm. at each sitting, gradually falling within a week or ten days to the normal 120 mm., at which place it may be usually maintained by regulation of diet, together with systematic exercise and occasional treatment. These cases are a very favorable class of cases, and can be kept for years from danger of advancing arteriosclerosis.

Class V constitutes those cases in which hypertension is found in individuals early in life—25 to 45 years of age. These patients may show a hypertension ranging from 130 to 180 mm., but manifesting no indication of arterial change. The condition is usually discovered on application for life insurance, or when examined for some other condition, and indicates the importance of the employment of the sphygmomanometer at all ages, even in childhood, when hypertension may be the forerunner of serious conditions, associated with so-called rheumatic and choreic conditions, as has been found when examining these young persons. There is probably no condition in which the inroads are so insidious and lead so progressively to arteriosclerosis as these early cases of hypertension; and no class of cases in which the physician is of such service to humanity in saving the young who will take his advice from the dangers of arterial degeneration and its consequences. If these patients, under a systematic régime of diet with exercise, are caused to lead a life free from the dangers of autointoxication which would result in hypertension and its consequences, life will be lengthened and rendered free from intercurrent affections.

Class VI includes young adults who have been upon college athletic teams, particularly the rowing teams of the great universities, and have developed cardiac hypertrophy with hypertension. In these cases, before failure is discovered, it must be insisted that a regulated amount of exercise is imperative in order to prevent a consequent thinning of the ventricular wall, leaving the subsequent perilous conditions of dilatation without hypertrophy. There is no reason why this condition should ever confront the physician if the dangers of over-exercise were properly recognized. When the condition is discovered before atrophy of the ventricular wall takes place, there is but one rule for life, and that is to maintain the hypertrophy by exercise.

Class VII constitutes the cases in which hypertension is compensatory owing to the presence of pathological processes in the path of the circulation, as of parenchymatous nephritis, cirrhosis of the liver, or the demands of excessive exercise, when hypertension may be observed without the presence of arterial changes. In this class of cases, particularly in parenchymatous nephritis, d'Arsonvalization is contraindicated, as the tension is compensatory. If the channels of circulation were then

*"The Treatment of Arteriosclerosis and Hypertension," *Journal of Advanced Therapeutics*, June, 1909.

opened, the blood would not be forced through the kidneys.

From the above classification, with the conclusions drawn with reference to the efficiency of the current in relieving hypertension with the prevention of pending calamities, a large field of indication is suggested for d'Arsonvalization. There is probably no one therapeutic measure which fills a more useful or wider scope of indication than the employment of d'Arsonvalization in cardiovascular diseases. The following cases will illustrate the effects under varying conditions:

Case I.—Mrs. S., aged 75, tension first taken in September, 1907. Pressure at this time was 212 mm., with no response to treatment. Treatment, however, evidently gave patient relief, and was continued almost daily until June, the following year. Pressure taken occasionally during the year remained constantly at 212 mm. The same treatment has been continued, except during the summer months, until the present time. There has been absolutely no change in the arterial tension and the general health of the patient has remained about the same. Her intelligence is unimpaired and there is so far no evidence of nephritis. Though the patient is now 79 years of age, there has been very little change in her condition during the past years. This case represents one of Class II, of which eight have been under observation during recent years, though none of them have received the constant attention of the case reported. It is evident in this case that there has been great benefit from the treatment in the matter of improving metabolism, though the arterial tension is not affected, and it is also a positive demonstration that the treatment does not depress the heart.

Case II.—Mr. C., aged 71, a retired civil engineer, came first under observation on May 9, 1908, with an arterial tension of 210 mm. At the first treatment his tension was reduced 15 mm. At the end of one month his pressure was 173 mm. before treatment, which had been continued almost daily during the month. During the following month, in which treatment was continued generally daily and occasionally on alternate days, the tension had gradually fallen from 160 to 155 mm. before treatment. The treatments were then continued on alternate days until August 10, three months from the beginning of his treatment, when his tension was 145 mm. before treatment. During August of that year, fifteen treatments were given and at no time was the pressure above 155 mm. after treatment. During the month of September ten treatments were given, during which time the disposition of the tension was to be somewhat higher, when daily treatments during the month of October were again resumed, and the pressure fell gradually to 182 mm. before treatment, and 170 after. This patient has been constantly under observation since this time, with variations ranging from 185 to 190 mm., occasionally rising again to 200, and a little above, when treatments were then given more frequently. In the month of October, 1908, pressure had once reached 190 and was always 165 or less after treatment. During this month eleven treatments were given. Beginning with June, 1909, the pressure ranged lower than during the preceding year. In February of that year but seven treatments were given and at no time did the pressure register above 175 mm. before treatment. During April the maximum was 185 mm., with a control of pressure with the usual fall of twenty mm. at each treatment. During the months of June, July, August, and September, 1909, the average pressure before treatment was about 180 mm. and the average after treatment 165 mm. During the fall and winter of 1909 the average pressure was 190 mm. with an average fall after treatment to 175 mm. Treatments were taken more frequently than during the summer months, cold weather seeming to cause a tendency to high pressure. The treatments were continued about the same during the winter of 1909 to July, 1910, when, during the summer months of this year, the pressure under less frequent treatments showed a disposition to a slightly higher range, averaging 195 mm., with an average fall to 180 after treatments. The patient has become familiar with the condition which indicate a rise of pressure, and treatment is administered less often and the relative reading is comparatively high. Before leaving for the country this year, after an absence of ten days, his pressure was 185 mm. and fell to 165, and he returned after one month's absence with a pressure of 170 mm. This case belongs to Class III and the results indicate the effect of autocondensation treatment upon cases of advanced arteriosclerosis, demonstrating the possibility of maintaining a reduction of tension which may be controlled by occasional or more frequent treatments at between 165 and 190 mm., avoiding the extremes of high arterial tension, otherwise certain to prevail. These cases present the most unfavorable showing made in any class of cases that respond to treatment.

Case III.—Mr. B., aged 74. Came under observation with a pressure of 193 mm. By daily treatments for three weeks this tension was gradually scaled down to 140 mm. At the end of this time treatments were given on alternate days and maintained at between 140 and 150 mm., gradually falling to 130 mm. Treatments were given after the second month, twice weekly, when the pressure was maintained between 130 and 140 mm. The frequency was gradually diminished to weekly and then bi-monthly treatments, until the present time. His pressure is now kept between 120 and 130 mm. by treatment once in two weeks. This patient has been judicious in matters of diet and exercise, and his physical condition has improved with the improvement in his arterial tension. This case may be classified as one of Class IV and represents a large class of cases and average result.

Case IV.—Miss L. B. C. This patient first came under observation in April, 1907, when urinary examination showed the presence of a heavy deposit of albumin with granular and hyaline casts. She was put under treatment with light baths and the static wave current was applied over the region of the kidneys. On July 1 the albumin and casts had disappeared and the patient left for her vacation in a good physical condition. On October 17, 1907, she returned, and her blood tension was found to be 190 mm. of mercury. She was then given regular autocondensation treatments, under which her blood tension gradually fell. On January 21, 1908, it was 125 mm.—a fall of 65 mm. Treatment was continued at intervals of a week until June 30, during which time her tension had ranged before each treatment from 130 to 145 mm., always falling approximately 10 mm. after each treatment. On December 9 her tension was found to be 110 mm. Her tension was not again taken until November 27, 1909; the urine was then free from albumin and granular and hyaline casts, and the patient had been

in excellent health. This patient had been living upon a restricted diet, owing to her nephritis, for more than a year before she came under observation, and with the diet unchanged, under the static, light, and vibratory treatment, the symptoms of nephritis had disappeared, but the tension had remained persistently high until autocondensation was employed, when it promptly fell from 190 to 120 mm., and has remained at an average of approximately 140 mm. ever since. There has been no recurrence of either albumin or casts. This case demonstrates the persistence of high blood tension under diet, which, under the same régime, with the added employment of high frequency autocondensation, had fallen and has remained within a range of safety for four years.

Case V.—Mr. H., an advertising man, came under observation December 6, 1909, with a blood tension of 260 mm. With daily twelve-minute séances until December 10 he came to the office with a blood tension of 215, and for the first time his tension fell below 200 to 190 mm. of mercury. Following this, the tension rapidly fell under daily treatments from the 12th to the 16th, when he came in with a tension of 180 mm. and it fell to 170 mm. after treatment. After an absence then of eight days without treatment, his blood tension was but 185 mm. and fell to 165 mm. following treatment. From that day his calls have been less frequent, and on January 10, 1910, he came to the office with a blood tension of 135 mm., which fell to 130 mm. after treatment. Since then his treatments have not been more frequent than once or twice weekly and at no time has his tension been above 145 mm. This patient had suffered for three years with headaches twice daily—in the morning and in the evening. These disappeared when the tension had fallen below 200 mm. Upon the institution of treatment the patient was put upon a restricted diet, promptly eliminating all meats, including fish, and also put on the use of the Metchnikoff plan of lactated milk diet, which he takes with a relish. The patient's own expressions of gratitude for his changed condition and improvement of the general physical condition, with the disappearance of dyspnea on exertion, were the best evidence of relief with the exception of the readings of the sphygmomanometer. With occasional treatments, whenever tension is disposed to rise above 150 mm. and attention to diet, this patient is now in excellent physical condition.

Case VI.—Mr. G., teacher, first came under observation January 21, 1910, when his blood tension registered 230 mm. Following the first twelve months of autocondensation it fell to 220 mm. Under daily treatments until January 25, inclusive, his tension upon entering the office was 175 mm. and fell to 155 m., after which he called on alternate days until January 31, when his tension fell after treatment to 140 mm. Treatments on alternate days were continued to February 26, when his blood tension was found to be, on entering the office, 120 mm., and no treatment was given. From March 10 to March 22 but two treatments were administered. On March 22 his blood tension was 138 mm. after ten days without treatment—only 3 mm. higher than at the end of the previous treatment. This patient continues well and with but moderate hypertension.

Conclusions.—(1) D'Arsonvalization is undoubtedly the most practical and efficient means of relieving arterial hypertension. (2) D'Arsonvalization produces no depression upon the heart and is consequently contraindicated in no cases of cardiovascular disease, except in those cases in which the hypertension is compensatory. (3) Except in cases of high blood pressure arising from other obstructing conditions, the tension should be lowered in all cases within a limit of safety, and maintained there by the conjoint employment of d'Arsonvalization and a diet limited in quantity and relatively free from purin bodies. (4) Under systematic routine management hypertension is thus usually controlled, the advance in most cases of arteriosclerosis delayed, and the dangers arising from complicating conditions deferred.

AN UNUSUAL CASE OF TYPHOID FEVER IN A YOUNG CHILD.*

By FREDERICK J. BARRETT, M.D.,

NEW YORK.

ASSISTANT PHYSICIAN, LINCOLN HOSPITAL, ASSISTANT IN CLINICAL MEDICINE, COLUMBIA UNIVERSITY.

Typhoid fever in young children is comparatively rare, and when it does occur often presents peculiar features differing essentially from the course of the disease in adults. Holt† states that he has never seen the disease in a child under two years old, and that it does not occur frequently until after the fifth year. Morse‡ in his report of 3,680 cases of typhoid fever from the records of the Boston City Hospital, found only 284 cases or 7.7 per cent. in children under fifteen years, and only 3 cases in children under five years. In this series there were no cases under two years. The disease in young subjects often presents such unusual features in onset, course, and individual symptoms, as compared to the adult type, that the difficulties in early diagnosis are very great. For these reasons the following case is of interest.

Edward X., 3½ years old, was admitted to the children's ward of Lincoln Hospital on February 28, 1911, at 5.30 A. M., with the following history: His father and mother are alive and well. He eats and sleeps well, but has been constipated from birth. He has never been ill until the present. For four days child has had loss of appetite, slight dry cough, feverishness, and increasing prostration, and has passed small, watery brown stools without blood. On the morning of the day before admission he complained of pain in his abdomen and twelve hours later had a hemorrhage from the bowels. It was not possible to ascertain the quantity.

On admission in the early morning, the temperature was 100°. The child was poorly nourished and markedly anemic. He was very restless and breathing rapidly, 48 per minute. The pulse was rapid, 132, small and weak. There was slight cyanosis of fingers and ears. The skin was dry and showed no eruption. The tongue was dry and heavily coated; the lips parched. The throat was normal except for slight hypertrophy of the tonsils. The superficial lymphnodes in the cervical region, axilla, and groin were palpable. The heart was normal in size and position, but the action was rapid and the sounds indistinct. The lungs showed scattered moist râles

at the bases posteriorly. The abdomen was somewhat distended, tympanitic over all, and soft. Palpation caused some apparent discomfort, but no localized tenderness was discovered. The liver and spleen were not palpable. The anal region was smeared with blood. The knee jerks were active. The Kernig and Babinski signs were not present. There was no nystagmus. There was a marked internal strabismus of the left eye, but this had been present from birth. Pupils were equal and reacted normally. During the day of admission the patient became actively delirious. The temperature fell at 8 A. M. to 96.5°, pulse 116, respiration 32. At 12 noon the temperature was 98.5°, pulse 152, respiration, 46. At 8 P. M., temperature 100.3°, pulse 132, respiration 32. At 10 P. M. the patient passed by rectum about 1,000 c.c. of bright blood. The delirium was very active and the child had to be restrained. He waved his arms about wildly and called constantly for his parents.

On the day after admission (the 6th of the disease) uranalysis showed an acid urine of a specific gravity of 1.030. There was no albumin nor sugar, but there were a few hyaline casts and a slight deposit of amorphous urates. The leucocytes were 19,600, of which 91 per cent. were of the polynuclear variety. There was no more bleeding from the intestine. The pulse was still rapid, but of somewhat better quality, probably owing to saline solution given by rectum by the drop method. The respirations were not quite so rapid. The lungs showed numerous moist râles over all. The nervous symptoms were as marked as on the previous day. The delirium was active and simulated closely that of meningitis. There was none of the low muttering nor subsultus tendinum seen in typhoid of the adult, but active crying and movements of the extremities. This delirium continued for six days. During this time the pulse was variable, showing several rates during a brief examination. The respirations ranged between 24 and 36, but were irregular. The neck was slightly rigid, but there was no retraction. The knee jerks were active. The Kernig sign became suggestive but not positive. The Babinski sign was positive on the left side. There were no eye symptoms. The lungs showed many moist râles over all, but no consolidation. During this time the temperature was irregular but never higher than 102.° Abdominal distention was relieved on the third day after admission by irrigation and the spleen was found to be not palpable. The bowels were moved daily with an enema. There was no roseola noted at any time.

The diagnosis during this time lay between typhoid fever and a general tuberculosis with meningeal, pulmonary, and intestinal involvement, with hemorrhage from a tuberculous ulcer of the intestine. The absence of a roseola and palpable spleen, the meningeal symptoms, and the intestinal hemorrhage were thought to be rather against typhoid, because of its rarity in young children and of the early stage of the disease. The high leucocyte count was explained by the hemorrhage and by a small abscess on the scalp.

On the second day after admission, the 7th of the disease, a Von Pirquet test was made with negative result. Through a misunderstanding blood for a Widal test was not taken at the time. On the 11th day of the disease lumbar puncture was done both for diagnosis and in the hope of relieving the nervous symptoms. About 15 c.c. of clear fluid was obtained under slight pressure. It was normal. The puncture, however, did relieve the active nervous symptoms. The child became much quieter and the general condition improved. The lungs cleared. The temperature assumed a remittent type for a few days and then fell to normal on the eighteenth day. Blood for a Widal test was finally taken on the fourteenth day of the disease and showed a positive result. This was confirmed by a subsequent test made during convalescence.

In review and with the diagnosis definitely made, the case stands out more clearly than in the first week during which the child was under observation. The one unusual feature is the hemorrhage. In all other respects the case fits closely Holt's description of the disease in children and corresponds with Morse's statistics. The short course of the disease, seventeen days (the average is three weeks), the remittent type of fever during the second week, the absence of the roseola, the absence of splenic enlargement, the fact that the intestinal symptoms (with the exception of the first week) were not prominent, and the marked nervous symptoms are common phenomena in the juvenile type of the disease. Holt states that "the typhoid of early childhood may be characterized as a fever more often with nervous symptoms than with intestinal symptoms." All three of Morse's cases under five years showed marked nervous symptoms, and one of them closely simulated meningitis, as did this case.

The intestinal hemorrhage is most unusual. In Morse's series of 77 cases under ten years old there were no cases of intestinal hemorrhage, and in 946 collected cases mentioned by Holt it occurred "in about 3 per cent. and the majority of these were in children over ten years old." The most frequent time of its occurrence is toward the end of the second week. In this case it occurred on the fifth day of obvious symptoms of the disease, although it is, of course, possible that a few days of onset were overlooked by the parents.

A feature of the convalescence in this patient was aphasia coming on toward the end of the febrile movement and lasting about three weeks. The child's mother says that he was always quite talkative and he became more so before he left the hospital, but during the period mentioned he was not heard to speak. There were no other nervous symptoms at this time and no paralyses were discoverable. The intelligence was apparently maintained during this time. Morse believes this phenomenon is probably due to a local anemia or edema. In other respects the convalescence was normal. The child rapidly recovered its strength, flesh, and color, and left the hospital on April 28 in excellent condition.

SALIVARY CALCULUS OF WHARTON'S DUCT.

By E. HARRISON GRIFFIN, M.D.,

NEW YORK.

A well formed manly little boy, nine years old, was brought to my office with the following history: A large tumor about the size of a bantam's egg had formed at the angle of his jaw, on his right side. This tumor had occurred at various intervals. It was attended with little pain at the start, when later all the symptoms of an abscess occurred and a discharge of purulent fluid took place from under the tongue through Wharton's duct. After several attacks of this nature, the mother would

press upon the enlarged submaxillary gland and empty the contents through Wharton's duct. She had a prescription for syrup of hypophosphites which she believed caused the lump to disappear in a short time and hastened the purulent discharge through Wharton's duct. The tumor had lasted for three or four days when the case was first brought to my office. The gland was hard to the touch and had the feeling neither of an abscess nor of a sebaceous cyst. The opening of Wharton's duct was slightly enlarged, red, and congested, but lacking any of the edematous swelling found in vanula. Pressure of the finger in this locality failed to show any abnormal condition. The mouth was slightly painful during mastication, but no other local or general symptom was manifested, except the swelling of the gland which had increased in size and was sensitive to pressure with a diffuse puffiniess of the submaxillary area somewhat analogous to that of the parotid in mumps.

I administered potassium iodide in doses of twenty grains, ordered a brisk cathartic, and asked the patient to return in two days. Upon his second visit he showed me a large calculus one inch in length and about the thickness of a stick of nitrate of silver; it was slightly pointed at the end which was the first to leave the duct. The sides were rough and looked like necrosed bone. It was white in color and had an appearance as if it had been added to by additions instead of forming at once into one mass. It broke into two parts in passing through the duct; after it had been in the air it turned to a gray white. It was hard and rough and had the usual look of any common calculus. Its passage had caused considerable pain. A direct examination showed a slight redness in the midst of the ostium umbilicale, the mucous membrane at this point was slightly swollen, tense, and hot, and pricking was complained of. These calculi have at times as a center a foreign body, such as a fish bone, toothpick, or straw, which has found its way into the body through Wharton's duct.

The following case reported by Delery is very interesting. A patient ate trout for supper; he awakened in the night with intense pain; respiration was difficult; expectoration very painful; the right sublingual and submaxillary region were swollen and extremely sensitive to the touch. In a few hours the pain involved the entire head and was so intense that the patient thought that he would go crazy. This condition lasted for three days. After this violent attack a respite occurred for six months, during which time the pain continued, but was endurable. After six months a fresh attack occurred, as violent as the first. The tongue began to deflect to the right and its movements were difficult. He then remained ten months without another attack, the tumefaction of the right submaxillary and sublingual region continued and was accompanied by exquisite tenderness. This condition continued for three years, with alternations of attacks and intermissions; the physician sounded Wharton's duct and found a stone. The operation was delayed until the next day. Hardly had the physician left the house, when the patient was taken with severe pains. Upon pressing his tongue over the sublingual tumor, he felt a pricking sensation. He looked into a mirror, noticed a point projecting towards the tongue, and recognized the calculus. This he removed. It was four to five lines in length and one and one-half in circumference. The fish bone projected from the calculus.

Rational Treatment of Diabetes in Hospital Practice.—Raolo Alessandrini says that since no medical treatment of diabetes has been successful in curing the disease we are obliged to depend on diet in its treatment. But in this respect we must not make any hard and fast rules to be applied to each case, since each case should be individualized, and the kind of diet must depend on the stage and cause of the disease, as well as the general condition of the patient. In the United Hospitals of Rome the ordinary hospital diet is given with the exception that sweets and farinaceous articles are excluded. It is well known that diabetics will not tolerate a diet consisting solely of meat. Carbohydrates cannot be entirely excluded from the food, and when they are removed it should be done gradually. After the carbohydrate tolerance has been established and sugar has disappeared the carbohydrates can only be returned to gradually. The three objects to be attained in treatment are to cause glycosuria to disappear, to prevent acidosis, and to avoid loss of weight. The last is not as important as the other two considerations. The diet should be such as to keep just below the limit of tolerance for carbohydrates. When the removal of carbohydrates does not stop the glycosuria we must lessen the amount of albuminoids, removing the meats and substituting vegetable albumins. An increase in weight is an indication of the good results of treatment. The amount of albuminoids given should never exceed 150 grams per day. As substitutes for sugar, inosite, mannite, and cellulose are all well tolerated. Alcohol is well tolerated and is of great value in diabetes. The daily dosage of sugar, the determination of the weight of the patient, the examination of the nitrogenous metabolism and the amount of ammonia in the urine are the guides in determining the number of calories to be given in the diet of diabetics.—*Rivista Ospidaliera.*

New Researches with Reference to Nongonococcic Ophthalmia, "Ophthalmia by Inclusions".—V. Morax has inoculated the eyes of monkeys with the discharge from the so-called ophthalmia by inclusions, which is not due to gonococcic germs, and has concluded from his examinations that there is a specific inflammation which causes this form of eye trouble in the newborn. The etiology is not known. This disease may be transmitted from an inflammation of the urethra or utero-vaginal membrane to the eye, and vice versa. It resembles trachoma in that there are granules, or epithelial inclusions, under the mucosa of the eyelids. The prognosis of this form of eye trouble is good, since it disappears spontaneously in a month or six weeks without ulceration or scar formation. No treatment seems to be of value in causing earlier disappearance of the trouble. Out of 119 cases of ophthalmia observed by Lindner, fifty-three were of this type.—*Annales de Gynécologie et d'Obstetrique.*

Salvarsan and Labyrinthine Troubles.—Eugene Felix cites many cases treated with 606 in which there have been ear troubles more or less severe. He advances the question whether these troubles have been due to the use of salvarsan, or have occurred in spite of its use as a result of the syphilitic virus. There are cases in which the auditory symptoms existed before the use of salvarsan and others in which the labyrinthine troubles followed the use of the injections. Ehrlich believes that these symptoms are only a recurrence of syphilitic manifestations and not due to the use of arseno-benzol. The author concludes that in order to avoid auditory troubles we should make a very careful examination of the acoustic organs of every patient who is to be injected with sarvarsan, and should exclude from treatment all cases that present auditory troubles, treating these cases with mercury.—*La Presse Médicale,* August 5, 1911.

THE CANCER CELL.

IT may be said with little fear of contradiction that the most interesting subject to-day in the whole field of medical research is the cancer problem. The study of it is world wide; in nearly every country of the civilized world special institutes exist for cancer research, some of them richly endowed by legacies from men who have themselves died of the disease. For many years the quest of the cause of cancer and of a means for its cure has gone on unremittingly, some of the acutest minds of the profession being devoted to it, and to-day, with theories too numerous for bare enumeration, we truly *know* absolutely nothing. The three favorite theories of the nature and causation of malignant disease are what may briefly be designated as parasitism, defective metabolism, and embryonic rests. The theory of parasitism flourished for a time and still has many convinced partisans, but to the observer from the outside it has seemed of late to be losing ground. Cohnheim's theory of embryonic rests enjoyed a brief revival when Beard promulgated his trypsin cure, but it does not appeal with convincing force to most investigators. Perhaps common belief inclines now more to the metabolic theory. According to this theory, preached for many years by Bell in London, metabolism is at fault in consequence of autointoxication or of a deficiency or depravation of one or more of the internal secretions, especially the thyroid; and because of this defect restraint on certain cells is removed and they then run riot in their growth, neglecting the functions they were intended to perform and giving themselves up wholly to a debauch of reproduction—becoming a sort of Jukes family, as it were, among cells. In all of these theories there is much that is unexplained, and one and all of them fail to answer satisfactorily all or even the greater number of the objections that may be raised against them.

Apparently equally short of perfection, yet exceedingly interesting in its novelty, is a theory advanced by Sir Henry Butlin in two Hunterian lectures delivered in London on November 13 and 18 (the *Lancet* and the *British Medical Journal*, November 25 and December 2, 1911). His conception of the nature of cancer is in a way related to both the parasitic and the metabolic theories, yet is distinct from either. His theory in brief is that the cancer cell is a tissue cell transformed into an independent entity—a cell "endowed with that wondrous gift which no man has seen and which no man can understand—the gift of life;" it has become a new thing, a new creation. The cell into which has thus been breathed the breath of life now becomes a veritable Frankenstein creation, warring to the death against the tissues from which it sprang. But what is it? In seceding from the metazoan organism has it returned to the primordial protozoa, in one bound leaping backward over the evolutionary chasm of eons, or is it a being of a new order? Butlin would place the new creature among the protozoa, for its resemblance to one of the parasitic protozoa is, he holds, very strong. Like these, the cancer cells spread in the interstices of the tissues in which they first appear. They are conveyed in the blood and lymph, they are deposited in distant tissues and organs, and they show the same predilection for certain tissues and organs as do the protozoa. They are like many of the parasitic protozoa in the fact that they live almost entirely by osmosis. Like the protozoa, they sometimes live for long periods of time in the body of the host without any sign of their presence, and perhaps in a state of lethargy, until their vigor and activity are restored by some lowering of the resistance of the host, or by some change in the part in which they had been lying which renders it more suitable to their necessities. Like many of the parasitic protozoa, they do not appear to furnish toxins which are dangerous to the health of the host, so that their effects are produced by mechanical causes—destruction of the tissues in which they live and multiply, and the stoppage of the blood-vessels and lymphatics. But the biologists will recognize no such nondescript and, as Butlin laments, they will have none of it, so he perforce creates for it a new order and a new name, calling it *Unicellula cancri.*

The cancer cell is thus itself the parasite, the neoplasm is not a tumor developed in response to the stimulation of a parasite, protozoan or bacterial, but is itself an agglomeration or colony of parasites. The cell being derived from a specialized tissue cell can produce only its like, and thus we have the various forms of carcinoma and of sarcoma remaining distinct and forming metastases like themselves. We have said the theory is, like all the others, not perfect, for it does not explain all the mysteries of cancer; but Sir Henry Butlin claims that it explains more of the phenomenon of malignant disease than any other; and it fulfils, he says, the conditions laid down by Koch—to wit: "A specific microorganism must be constantly associated with a given disease; it must be isolable and studiable apart from the disease, and when introduced into a healthy animal it must be able to reproduce the disease in that animal; and in the animal in which the disease has thus been experimentally reproduced the organism must be found under the original conditions." The only one of these conditions, the fulfilment of which might be disputed, is that which demands that the cell is isolable and studiable apart from the disease, but this Butlin claims has already been demonstrated by Carrel and Burrows who have grown cancer

cells in artificial media. This is indeed true, but herein is the weak spot of Butlin's ingenious theory, for tissue cells as well as cancer cells have been grown in artificial media. Unless, therefore, Sir Henry can prove that the transfer of these from the living body to the culture media endows them with the life principle, his distinction between the tissue cells and the cancer cells falls to the ground. "Implant the normal cell," he says, "and you cannot make it live. Implant the cancer cell, and you cannot kill it"—but if the tissue cell does *not* perish when implanted or when transferred to culture media, as Carrel and Burrows have apparently demonstrated, we must assume that it is equally alive with its erring brother of the malignant neoplasm—as it is, for life surely resides not only in the organism as a whole, but in each of the individual cells of which it is formed.

NEW ORLEANS AND THE PANAMA CANAL.

Writing in the *New Orleans Medical and Surgical Journal*, November, 1911, Howard D. King of New Orleans sounds a note of warning. He refers to the menace of plague which will threaten the Southern States upon the opening of the Panama Canal. It has been predicted that the canal will convert New Orleans into the greatest export and import market of the New World. Material prosperity, however, invariably brings in its train evils of many descriptions. "Trade follows the flag" and "disease follows trade." Moreover, the ports of the Southern States and especially the port of New Orleans will be brought into close relationship with lands in which devastating epidemic diseases, particularly the plague, are rife. King notes that the plague situation in South America is already sufficiently alarming but will necessarily become even more so with the completion of the Panama Canal. This aspect of the matter seems to be ignored to a great extent as inconvenient and subversive of trade interests. The lay press disregards it as much as possible and in the laudatory articles on the Panama Canal no mention is made of the menace of disease. Plague, in fact, appears to be the skeleton at the feast.

According to King our main source of danger from introduction and dissemination of plague on American shores is not as so many believe from direct communication with the now infected ports of the Far East, but is to be found in South America. "It is the existing infection in South America which threatens our safety, and it behooves us to exercise the greatest caution in repelling the invasion of this traveling disease. The presence of plague in New Orleans or other Gulf ports would imperil the entire country. Thus, to-day, we stand facing a problem, the solution of which cannot be undertaken too early." It is well known that the entire western coast line of South America is now infected, while on the eastern coast the infection is distributed in spots and does not follow a continuous line. There are other facts of a sinister nature. Knowledge as to the exact conditions prevailing in South America is lacking. This in itself is unfortunate and may lead to disaster. Then it is only too well known that the conditions in most of the South American coast towns lend themselves most favorably to the dissemination of plague. To be sure sanitary measures are in force in South America, but, perhaps, as a rule, these methods are not in complete consonance with modern laws of sanitation as understood in most civilized countries. The Latin peoples of South America are jealous of European or other outside interference and are complacently satisfied that their own methods of sanitation are quite satisfactory. Indeed in some parts of that continent indifference prevails as to the existence of disease. All these facts combine to render the situation a menacing one. King advocates a uniform international system of maritime sanitation and fumigation, arguing that the ordinary measures used in combating the plague are inadequate and antiquated. Finally, he rightly insists that the United States at least should put its own house in order and so improve the sanitary conditions of New Orleans and other Southern ports that the risk of plague invasion by way of the Panama Canal will be minimized. Both in New Orleans and elsewhere there is scope for the display of unlimited energy in this direction. The promotion of trade deserves encouragement and material prosperity is doubtless a goal to be eagerly sought. But these will be dearly bought if at the same time plague is introduced. To be warned in time is to be forearmed, and it is to be hoped that such may be the result in this instance. Were the opening of the Panama Canal to be followed, or better preceded, by a thorough housecleaning, so to speak, in South America and in the Southern States it would be a cause for international rejoicing. At any rate this country should lead the way by the sanitary regeneration of such ports as New Orleans. It would ill become us to point the finger of scorn at other countries for neglect of modern methods of sanitation while we continued to disregard similar precautions in our own ports.

THE ARMY MEDICAL DEPARTMENT IN THE FIELD.

The prime function of the medical officer in time of peace or of war is the prevention of disease. In addition, during the progress of a campaign, he must provide for the prompt segregation and care of the sick and wounded. The army must be kept in proper condition as a dangerous fighting machine and every other consideration must be subordinated to this end. This is the keynote of an article by Lieut.-Col. Frank R. Keefer, in the *Journal of the Military Service Constitution*, November and December, 1911. As to the sanitary service in camp, one of the most important functions is the supervision of the water supply. If this is polluted then disease is certain to follow. Thus, the water supply must be carefully guarded, frequently inspected as to pollution, and purified by special means if necessary. Strict precautions must also be taken to destroy the fecal deposits. Neglect of such measures have been invariably followed by disastrous results, even in the most modern campaigns. In war time the care and removal of the sick is the

chief duty of the department, while a not uncommon additional duty is "the management of epidemics among the inhabitants of a country under military control, to prevent infection of new territory or of the army."

Lastly, the writer describes the functions of the Sanitary Service in combat and calls attention to the fact that the great changes in battle tactics, necessitated by increased range and rapidity of fire, have largely altered the conditions to be met by sanitary troops. It is shown that the medical officers and War Department of this country are fully alive to these changed conditions and are keeping abreast of the most recent innovations in this direction. The author concludes his admirable paper in the following words: "It is universally accepted that the most important factor in the efficiency of an army is its health. It therefore appears that the Medical Department, by its functions of the prevention of disease and the prompt removal of the disabled from the line of action, promotes military efficiency and aids greatly the winning of victories and the following up of advantages gained."

STEVENSON AT SARANAC LAKE.

At Saranac Lake is the Adirondack Cottage Sanatorium, the beneficent institution now world-famous as that begun some three decades ago by Dr. Edward L. Trudeau, himself once a sufferer, and the American pioneer in the modern treatment of tuberculosis. During those 30 years many men and women notable in literature and the arts have visited Saranac Lake—some as visitors only; probably a much larger proportion in efforts frequently successful to become again whole in body. Intellectuals, indeed, "hard students, divines, physicians, philosophers, deep lovers, zealots in religion," have ever paid dreadful tribute to the Captain of the Men of Death. But none among those many who have come to Saranac Lake have ever inspired so much interest as did Robert Louis Stevenson; nor does to-day the memory endure as it does of him, who, in the fall of 1887, accompanied by Lloyd Osborne, his stepson and co-litterateur, took for the winter the yellow Baker cottage. Later his mother joined him there. And ever since its occupancy by Stevenson has this cottage been an object of interest to visitors, temporary residents, and townsfolk. One hardly steps from the train when comes the question, "Don't you want to see the yellow cottage that Robert Louis Stevenson occupied?"

That Adirondack winter was trying for Stevenson; his health improved, but his exotic nature found it hard indeed to endure the ice and the snow and the bitter cold. His cottage had a large fireplace, where he had logs ever burning briskly. The bleak banks of snow without did not appeal to Stevenson, though as early as four in the afternoon the darkness came to hide them. The great novelist of the *outré* preferred to sit by the log fire, watch the fantastic flames, and talk. Windows were tightly shut and he smoked cigarettes incessantly, until the smoke mist rolled over the fireplace to the windows and made, in itself, a blanket that shut out the sight of the snow. Dr. Trudeau, who visited him frequently, has observed that Stevenson "used to rail in such forcible but beautiful and picturesque language at the cold, at the snow, at the cloudy days and the succession of them, and the lack of color and sunshine. His idealistic and artistic temperament clung to all that was beautiful in life as expressed in nature, in art, in form, light, and color, in thought, in poetry, and in imagination. He deliberately turned his back on the cold facts of science and life, ignored them as much as possible, and shunned the discussion of such subjects as poverty, disease, sorrow, and suffering, with which we were more or less surrounded."

On Saturday afternoons Stevenson made it a practice to be "at home" to those who wished to call. Any one might come; and many took advantage of the opportunity. But he seemed to get little pleasure out of these functions. Conversation quickly tired him. A persistent "fashionable lady" seemed especially a *bête noire*, and one day after she left, Stevenson observed, "It isn't the great unwashed which I dread, but the great washed." But from one visit Stevenson derived only unalloyed satisfaction and delight. This was when Richard Mansfield came to the Baker cottage. In the living room, while Stevenson sat by the log fire, which fitfully and uncertainly lit up the room, Mansfield on a table in a corner of the room gave his marvelous and gruesome impersonation of "Dr. Jekyll and Mr. Hyde."

It is odd how the quality of a genius, if he be a consumptive, is likely to be affected by that disease. The phenomenon occurs too frequently, in literature at least, to be explained solely on the basis of individual temperament; it must come about by reason of the effect upon the psychism of the toxins evolved by the specific bacteria. Robert Louis Stevenson is preeminently a case in point. Certainly there are no more fascinating contributions to literature than the works of this sick hero, who was ever an optimist despite the most dreadful reasons for being the reverse. Consider any number of passages and incidents such as the pretended death and burial in the "Master of Ballantrae"; the scaring nearly to death of the boy in the inn by the tramp of the blind pirate in "Treasure Island," and many others. Again, in the "Bottle Imp" the incident of the two men viewing the bottle of iridescent glass, within which was vaguely seen some strange thing moving about; how one of these men, his curiosity becoming too much for him, for an instant uncorked the bottle; how, then, upon a glance within, his face grew ashen-green, from which moment he was ever a sick and stricken man. "Dr. Jekyll and Mr. Hyde" is full of such morbid touches—especially the ghastly turning of the doctor's benign features into the hideous face of his devil nature in the upper story window that calm Sunday afternoon. In "St. Ives," the "Body Snatcher," and other stories by Stevenson is the like literary pathology manifested; and the reason may lie in those tuberculous toxins which were coursing in his blood.

Direct Contagion in Measles.

In the *Military Surgeon*, October, 1911, is a report of an epidemic of measles in Columbus Barracks, Ohio, with some remarks on the manner of transmission of disease by Captain Arthur C. Christie, Medical Corps, U. S. A. The special interest in this paper lies the remarks on the manner of transmission and in the writer's view that measles is a more serious disease by far than it is generally thought to be. As for the mode of transmission, Christie is a strong believer in the more recent views in this respect, that the organisms of disease die quickly after leaving the body of the patient, that is, of a patient who has either recovered or died. In the case of yellow fever and malaria the belief that the disease was conveyed chiefly by fomites has been exploded. Christie argues that when the difficulty of keeping alive and cultivating the known organisms of disease is considered and when it is known that most of them require the most favorable conditions of culture media, temperature, and moisture in order to remain living and virulent, it does not seem reasonable to believe that the causative organisms of measles, scarlet fever, etc., could remain alive and retain their virulence on dry clothing, a bare wall, or other such locality so unfavorable to their growth. He therefore is of the opinion that so far as measles is concerned it seems reasonable to believe that in most cases the disease is contracted from persons in the early catarrhal stage, before it is diagnosed and the person is isolated. Hence, the preventive measures to be applied when the disease is prevalent are to diagnose in the early stage and to isolate promptly. The epidemic in Columbus Barracks has been widespread and virulent in type and the complications of a severe kind and somewhat numerous, which goes to substantiate Christie's contention that measles is a serious disease.

A New Editor of the "New York Medical Journal."

Announcement is made of the appointment of Dr. Charles E. de M. Sajous of Philadelphia to be editor of the *New York Medical Journal*, succeeding the late Dr. Foster, who had held that office from the foundation of the journal to the time of his death. Dr. Sajous is well qualified by a long editorial experience for the work he has undertaken. He was born in 1852 and was graduated from the Jefferson Medical College in 1878. He began practice as a laryngologist but soon took up editorial work. He founded in 1888 the *Annual of the Universal Medical Sciences*, which he conducted with the collaboration of many physicans in America and Europe, until the publication was abandoned in 1893. This was followed in 1898 by the "Cyclopedia of Practical Medicine," the seventh edition of which is announced as in preparation. Dr. Sajous is best known, however, for his monumental work on the "Internal Secretions and the Principle of Medicine," published in two volumes in 1903 and 1907, which established his reputation as an original worker and clear thinker. Dr. Sajous, it is stated, will continue to reside in Philadelphia and will retain his hospital and consulting practice, but will give up his visiting practice in order to devote the time so gained to his editorial work for the *New York Medical Journal*. Our contemporary is to be congratulated on having secured as editor a physician of such high standing and authority.

News of the Week.

New York the Healthiest of Cities.—According to the statement of the Health Department officials there are no other large cities in this country with a minimum weekly and monthly record that can compare with that of New York and with only two weeks remaining in the year it seems a foregone conclusion that the year's record will be the best yet recorded. Last year Boston's death rate was 16.3 per 1,000 population; Chicago's, 15.38; Washington's, with its 3 per cent. colored population, 18.28; while New York's death rate was 15.96, leaving Chicago slightly in the lead. For the eleven months of 1911 New York's death rate has dropped to 15.19, with every prospect of sending the figure below 15 for the present month. The lowest monthly record was for October, when the rate was 12.99 per 1,000 population. This record is as low as that of any rural community in the country. A study of mortality tables shows that there has been a decrease in the prevalence of infectious and communicable diseases, those amenable to public sanitary control; while, on the other hand, the causes of death, such as cancer, heart and kidney troubles, and diseases of the liver, which are outside the influence of sanitary intervention, showed a considerable increase in mortality.

Low Death Rate for New Jersey.—The State Registrar of Vital Statistics reports that for the month of November the deaths numbered 300 less than the average for the past twelve months. Of the 2,914 deaths reported, 588 were infants under one year of age, 243 children from one to five years of age, and 936 persons over sixty years of age.

Vital Statistics for the District of Columbia.—Deaths for the year 1910-1911 number 6,511 as against 6,212 in 1909, including 3,199 during the first six months of 1911, which must be considered in order to round out the period covered by the report; while in 1910, for the same period, there were 3,397 deaths recorded. Infantile paralysis has stood out prominently. Although there is no law making this disease reportable, the Medical Association of the District of Columbia in its investigation found 506 cases. The births recorded during 1910 numbered 7,031, an increase of 5 per cent. over the preceding year. Thus far for the present year the births number 3,413.

New York City Has Less Typhoid Than Usual.—According to a statement issued by the Department of Health there has been less typhoid fever than usual in New York City during the past year. The average number of cases yearly for the past five years is 3,379. This year there have been 3,140 cases, as compared with 3,370 in the twelve months of 1910. Since December 1, 92 cases have been reported.

Hookworm Disease Prevalent in Texas.—Following the investigation of Dr. C. W. Stiles of the United States Marine-Hospital Service as to the prevalence of hookworm infection in the State of Texas, Dr. Stiner, Health Officer of the State, has issued a report stating that hookworm infection was found to be present in forty-five counties of the State, from 30 to 40 per cent. of the children in the rural schools being affected. Evidence of infection among the teachers was not entirely lacking. The report states that owing to the increasing number of shade trees and to the loose and sandy soil there is need of more careful attention to sanitary conditions than in many other localities.

Death from Pellagra in New Jersey.—The first death from pellagra recorded in New Jersey occurred in St. Michael's Hospital, Newark, on November 29.

Petition to Restore the U. S. Army Canteen.—Under the leadership of Dr. W. W. Keen of Philadelphia, a petition has been prepared for presentation to Congress and signed by 275 physicians from all over the United States urging the restoration of the canteen in the Army. After giving the history of the canteen in the Army the petition goes on to say that it is the practically unanimous testimony of all the general officers and post commanders that since the abolition of the canteen in 1901 intemperance has increased and that there has been a corresponding increase in infractions of discipline and desertions. The restoration of the canteen is urged on the ground that soldiers are driven to resorts outside of the posts, resorts of the lowest sort, where they not only drink strong liquors but contract venereal diseases, and that it is most unwise to increase the moral and physical risks of the military environment of these men by act of Congress. The bill points out that not only in the interest of the soldiers but for the welfare of their future wives and children Congress should reestablish the canteen in the Army by the passage of the Bartholdt bill.

Pennsylvania Bureau of Medical Educational Licensure.—Governor Tener has appointed the following to membership in the new State Board of Medical Educational Licensure, which with the beginning of the new year will succeed the old three-board Medical Council: Dr. Samuel G. Dixon, State Commissioner of Health, and Nathan C. Schaeffer, Superintendent of Public Instruction, ex-officio; Dr. Adolph Koenig of Pittsburgh, representing the Medical Society of the State of Pennsylvania, for three years; Dr. G. A. Mueller of Pittsburgh, representing the Homeopathic State Medical Society, and Dr. C. L. Johnstonbaugh, of West Bethlehem, representing the State Eclectic Society, each for two years; Dr. D. P. Maddux of Chester, representing the Homeopathic State Medical Society, and Dr. J. M. Baldy of Philadelphia representing the Medical Society of the State of Pennsylvania, each for one year.

Connecticut's Health Report for October.—This report shows that the death rate for the large towns was 14, for the small towns 14.3, and for the whole State 14.1 per 1,000. There were 36 more deaths than the average for October for the past five years. The report announces that the Legislature appropriated $8,000 for the free distribution of antitoxin, which will be made through the general drug trade. Only tetanus and diphtheria antitoxins will be furnished. The State Board of Health has adopted the following regulation: "It shall be unlawful on and after January 1, 1912, to provide a common drinking cup in, or upon, the premises of any public building, hotel, restaurant, theater, public hall, schoolhouse, or store, and in any public park, street, railroad, or steamboat."

Vaccination Against Typhoid in Buffalo.—It is announced that the City of Buffalo will adopt the method of vaccination against typhoid fever employed in the army. The Health Department is prepared to furnish the antityphoid vaccine to physicians and nurses for immunizing purposes.

The Prevention of Blindness was discussed at a public meeting held last Friday, December 8, at the Young Men's Christian Association in Paterson, N. J., under the auspices of the New Jersey Commission for the Blind. The meeting was addressed by Douglas C. McMurtrie, secretary of the American Association for the Conservation of Vision, who called attention to the extent of preventable blindness and described the Credé method of prophylaxis against ophthalmia neonatorum. He also urged legislation to compel the reporting of infantile conjunctivitis and the introduction of hygienic measures to check the spread of trachoma in certain sections, and spoke of the advances being made in the installation of safety devices for the prevention of injuries to the eye. Miss Lydia Y. Hayes, supervisor of work for the blind in New Jersey, described the educational and preventive activity in that State.

Railroads Must Furnish Individual Drinking Cups.—The Public Utility Commissioners of the State of New Jersey have issued an order ordering all railroads in the State to provide a drinking cup for each passenger after January 1, 1912. When the recent law prohibiting public drinking cups went into effect the railroads failed to comply with it, and as a result complaint was entered with the commission, which has decided that facilities for the use of drinking water by passengers are part of an adequate and proper service.

What "Practitioner" Means in Missouri.—The status of a medical practitioner in Missouri has been defined in a decision by the Supreme Court in the case of a man convicted of practising medicine without a license. Part of the decision is as follows: "The practice of medicine is not confined to the administration of drugs; nor is surgery limited to the knife. When a physician advises his patient to travel for his health he is practising medicine. Broadly speaking, one is practising medicine when he visits his patient, examines him, determines the nature of the disease, and prescribes the remedy he deems appropriate."

Must Report Emergency Cases.—In Portland, Ore., a city ordinance has been passed compelling all hospitals to keep a record of emergency cases and to report them immediately to the police department under penalty of $200 fine or imprisonment for thirty days. It is believed that this ordinance will be especially useful in bringing to justice those responsible for automobile accidents that result from speeding.

Too Many Medical Schools in the South.—President Alderman of the University of Virginia is reported as saying that there are entirely too many medical schools in the Southern States. He says that there are at present fifty-seven medical colleges where four would be sufficient. The South now contains one physician for every 760 people, while Prussia has but one for every 2,000 and considers herself overstocked. Last year there were 1,300 physicians graduated; 490 would have served all purposes, making due allowance for deaths and increase in population.

Chicago Health Board Asks for Larger Appropriation.—Commissioner George B. Young has asked for an appropriation of $300,000 to build an isolation hospital for contagious diseases and $50,000 for two new public bath houses and the enlargement of three others. The entire appropriation asked for is $1,186,030 or over $500,000 in excess of that of 1911.

A Fund for Nurses' Pensions.—The Superintendent of Mount Sinai Hospital announces that a

fund of $60,000 has been completed for the relief of nurses who, after graduation from the Mount Sinai Hospital Training School, have supported themselves, at least in part, by nursing the sick for a period of twenty years. In exceptional circumstances relief may be given to nurses who have become incapacitated before that time. The fund is to be administered by a committee of the Mount Sinai Alumni Association.

The Northwestern University of Chicago has purchased land on Dearborn street, adjoining the medical school, for approximately $150,000. This property is to meet the present and future needs of the medical school.

Tarrytown Hospital Opened.—The hospital at Tarrytown, N. Y., was opened on December 9. It is said to be the most completely equipped and best arranged small hospital in this country. It was built at a cost of about $80,000, a large amount of which was given by Mr. John D. Rockefeller, Mr. and Mrs. John D. Archbold, and Miss Helen Gould.

The Rockefeller Institute of Medical Research in New York City has secured the title to Sixty-fifth and Sixty-sixth streets, from Avenue A to Exterior street. The Institute owns all the property from Sixty-fourth to Sixty-seventh streets and from Avenue A to Exterior street, and now that there is no possibility that the city will cut streets through the plot extensive building operations which have been planned will be undertaken.

Kanopolis Offers Site for Hospital.—This town, which is situated near Ellsworth, Kan., has offered to provide a site for the State sanatorium for tuberculosis, for which funds were appropriated at the last Legislature.

The United States Marine Hospital on Remington avenue, Baltimore, is to have its present buildings remodeled and newly equipped and an addition built.

The Bellevue Hospital of San Francisco has filed a petition in voluntary bankruptcy. Its debts amount to $9,320 and its assets to $1,611.

Gifts to Charity.—The Saturday and Sunday collection for the relief of the sick poor of St. Louis has now reached $42,429, and it is believed that when all contributors are heard from the amount will equal or exceed that of last year, which was $44,535. Under the will of John J. Clancy of New York City $25,000 each is given to the Presbyterian, St. Vincent's, and Mount Sinai hospitals, and $10,000 to St. John's Guild. Mrs. Charles W. Dabney of Dedham, Mass., has given $5,000 to establish a free bed in the Middlesex Hospital at Middletown, Conn.

Dr. Arthur D. Bush of Wakefield, Mass., has been appointed instructor in physiology in the University of Vermont.

Dr. H. N. Kierulff of San Francisco has been appointed prison physician to the State Penitentiary at San Quentin, Cal.

Dr. Harry S. Lewis has been appointed Superintendent of the Emergency Hospital at Washington, D. C., to succeed Dr. E. P. Magruder, who recently resigned.

Dr. Edward J. Clark of Lowell, Mass., has been elected superintendent of the Lowell Hospital.

Dr. John P. Munn has been elected president of the New York University Athletic Association. He has made a gift to the association in the form of cups and medals to be competed for in the intramural sports.

Appointments to Medical Faculty of Leland Stanford University.—The Board of Trustees of this institution announce that Dr. H. E. Alderson will be Associate Clinical Professor of Medicine, his work beginning September 1, 1912, and will have charge of the dermatological clinic. Dr. L. Porter, now Professor of Pediatrics at Cooper Medical College, San Francisco, will affiliate with the university on January 1.

Removal.—Dr. Newton M. Shaffer has removed to 17 East Thirty-eighth street, New York.

The West Wisconsin District Medical Society, which met in Eau Claire on November 27, elected the following officers: *President,* Dr. J. V. R. Lyman; *Secretary-Treasurer,* Dr. E. E. Tupper.

The Fifth District Medical Association at its semi-annual meeting in San Antonio, Tex., on November 25, elected the following officers: *President,* Dr. W. T. Dawe of Gonzales; *Secretary,* Dr. H. H. Ogilvie of San Antonio; *Treasurer,* Dr. W. C. Williams of Staples.

Obituary Notes.—Dr. Sidney Buffington, a recent graduate of the Medico-Chirurgical College of Philadelphia, died in Philadelphia on December 5.

Dr. William C. Parry died of pneumonia at his home in Hainesport, N. J., on November 28. He was a graduate of Jefferson Medical College, Philadelphia, in 1872, and served in the State Senate for three years.

Dr. Walter Edwin Carll died at his home in Oregon City, Ore., November 29. He was born in 1858 and was graduated from Harvard Medical School in 1885.

Dr. James Martin Ruchton died at his home in Johnstown, S. C., on November 28 at the age of 42. He was a graduate of the Medical College of Georgia in 1899.

Dr. David Corwin Bice, a graduate of the University of Iowa State College of Medicine, Iowa City, in 1875, died in Denver November 25.

Dr. Albion S. Whitmore of Boston, Mass., a graduate of the College of Physicians and Surgeons, Columbia University, New York, 1894, died December 2. He was a member of the American Medical Association, the Massachusetts Medical Society, and the Boston Medical Library Association. He was 60 years old.

Dr. George L. Rice of North Adams, Mass., a graduate of George Washington University Department of Medicine in 1862, died in Salamanca, N. Y., November 27, at the age of 73 years.

Dr. John F. Young of Newburyport, Mass., a graduate of the College of Physicians and Surgeons, Columbia University, New York, in 1868, died December 4. He was 69 years old.

Dr. Charles J. Creighton of Redlands, Cal., a graduate of Rush Medical College, Chicago, Ill., in 1879, died November 25, aged 69 years.

Dr. Lucius Deyampert Webb of Greensboro, Ala., died at his home on December 1 after a long illness, at the age of 64 years.

Dr. Joseph E. MacNeill, formerly of Chicago, died in Waukesha, Wis., on December 3 at the age of 74 years.

Dr. Martin Schnabel, a graduate of the University of California in 1873, and formerly of Sacramento, died at his home in Newcastle, Cal., on November 22.

Dr. John F. Young, a graduate of the College of Physicians and Surgeons, New York, in 1868, died at his home in Newburyport, Mass., on December 3, after an illness of more than two years.

A PROFESSIONAL ENDORSEMENT OF DR. DOTY.

On Wednesday evening of this week some thirty-five physicians of this city, representing all branches of professional activity—general practitioners, specialists, laboratory workers, editors—met at the Academy of Medicine for the purpose of declaring publicly their confidence in the Health Officer of the Port of New York, Dr. Alvah H. Doty, and their approval of his efficient administration of quarantine. Among those present were Drs. Robert Abbe, Gorham Bacon, Hermann M. Biggs, George E. Brewer, John W. Brannan, Algernon T. Bristow, W. F. Chappell, Charles L. Dana, George A. Dixon, William K. Draper, Simon Flexner, Rowland G. Freeman, J. H. Girdner, L. Emmett Holt, A. Jacobi, Walter B. James, Theodore C. Janeway, Alexander Lambert, John A. McCorkle, Walter Sands Mills, William P. Northrup, William H. Park, Wendell C. Phillips, William M. Polk, T. Mitchell Prudden, Beverley Robinson, A. A. Smith, M. Allen Starr, T. L. Stedman, George M. Swift, J. S. Thacher, W. Gilman Thompson, R. J. Wilson, and Joseph Winters. Dr. Jacobi presided. After a general discussion of the quarantine situation and of the danger to which New York and the entire country would be exposed were an inexperienced man in charge of the service during the coming summer, with its threat of a cholera invasion, the following preambles and resolution, offered by Dr. Prudden, were unanimously adopted, signed by those present, and forwarded to Governor Dix.

The undersigned, physicians and citizens of the city of New York, at a conference held in the interests of the public health, on December 13, 1911, unanimously adopted the following preambles and resolution:

Whereas, The effective and conservative administration of the maritime quarantine service at the Port of New York is of the greatest importance to the health of the people of the city and State of New York, as well as to all citizens of the United States; and

Whereas, The successful performance of the duties of the Health Officer of a great port like this requires that the incumbent shall be a man of wide knowledge and experience in the detection and treatment especially of infectious diseases; that he shall be thoroughly grounded in the principles and trained in the practice of modern sanitation; that he be fully informed as to the sources of infection in other lands and in close touch with the measures in vogue at all ports of embarkation to reduce the risks from infected immigrants; that he be a man of such experience and achievements in maritime sanitation and the administration of quarantine that he will secure the cooperation of the Health Officers of other ports in this and other countries in the control and suppression of communicable diseases; that he be a man of demonstrated capacity to successfuly control the serious emergencies which frequently arise in maritime sanitation, especially at a great port; and, finally, that he be keenly and intelligently alive to the welfare of detained passengers and to the vast interests of commerce so often seriously affected by the necessities of quarantine; and

Whereas, Dr. Alvah H. Doty has conducted the quarantine service at this port for about sixteen years, skillfully and wisely, with admirable devotion to the public welfare and with remarkable success; he has kept the service at this port steadily abreast of the new knowledge which, year by year, scientific discovery has recorded. He has devised and perfected new methods in the detection and prevention of disease which have been widely followed. He has, little by little, as the State appropriations would permit, initiated and perfected far-reaching and important improvements in the quarantine plant and in the methods of administration, all of these contributing to the efficiency of the service and to the welfare of the persons and commercial interests involved. In this service Dr. Doty has secured wide recognition the world over for his successful contests with disease and for his important contributions to the principles and practice of maritime sanitation. He has won the cordial personal esteem of those devoted to the interests of the public health. He has achieved distinction for his State in his conduct of a trying and responsible office, the duties of which he has carried out with rare devotion to the high aims which preventive medicine cherishes. Dr. Doty's wide knowledge of practical sanitation in all its forms; his exceptional personal familiarity with the nature and control of communicable diseases in all parts of the world; his long experience in the quarantine service at this port; his successful control of serious emergencies when plague, cholera, smallpox, yellow fever, and other lesser maladies have been the subjects of great concern; the close touch and cordial relationships which he has maintained for many years with the Federal and other quarantine authorities—these qualities and achievements of Dr. Doty have year after year given steadfast assurance of safety to the personal and commercial interests which are sometimes subject to disquiet and damage in the face of threatened epidemics of contagious disease.

During the last twenty years, it was only in the late summer and the fall of 1892, before the present administration of quarantine, that the presence of cholera in this city caused general and local acute apprehension. At that time the eleven cases in the city reported by the Health Department caused grave national, State, and city fear concerning personal security and business enterprise. During the last season, however, 1911, the almost constant presence of cholera at Quarantine and the two outside instances due to cholera carriers caused no apparent fear in the public mind nor in the conduct of business affairs and certainly incited no apprehension in the medical profession, chiefly, as we believe, because of the unlimited confidence reposed in Dr. Doty by all those concerned in public welfare and security.

Whereas, Finally, while Dr. Doty has successfully controlled the threatened invasion of Asiatic cholera at this port under extremely onerous conditions during the past two years, it is probable that again in the coming season we shall face the dangers of infected immigrants of equally serious import; and since it is highly important for the common welfare in this State and throughout the country that none of the administrative safeguards against disease which have been so successfully and humanely maintained in the past shall be in any way or measure diminished; be it therefore

Resolved, That we earnestly and respectfully request that His Excellency John A. Dix, Governor of the State of New York, reappoint Dr. Alvah H. Doty as Health Officer of this Port, and that in the interests of the public health at large, in the interests of commerce, and for the welfare and comfort of those who travel by the sea, this appointment be made at an early day.

Correspondence.

IPECAC IN DYSENTERY AND TYPHOID FEVER.

To the Editor of the Medical Record:

Sir:—The letter from Dr. Albert H. Buck, in your issue of December 2, brings back also to me pleasant memories of my service in the New York Hospital with Dr. Buck, 1868 and 1869, when active therapeutics meant more than many seem to believe at the present day.

I want to confirm strongly what Dr. Buck says in regard to the successful use of ipecac in the many cases of dysentery which came from the South; these cases were mainly among sailors, who were entered as C.H.S., that is, Custom House Subject, meaning those sent by the government, with which the hospital had a contract, before the days of the Marine Hospital service. My father, the late Dr. Henry D. Bulkley, attending physician, also made use of this measure, and I remember well the large boluses of powdered ipecac which the patients took with such happy effect. It was also during my service that the late Dr. E. C. Seguin, house physician, whom I assisted, introduced the hypodermic use of quinine, which was often given in the terrible cases of malarial fever on arrival of the sufferer from Panama, often in the algid stage, saving life in many instances.

L. Duncan Bulkley, M.D.

New York.

MINERALIZATION IN THE TREATMENT OF PULMONARY TUBERCULOSIS.

To the Editor of the Medical Record:

Sir:—In an article in the *Medical Herald,* June, 1908, I maintained that the cause of pulmonary tuberculosis is a lowered blood pressure which prepares the soil for the tubercle bacillus. By the administration of mineral salts the blood pressure is raised, the protective action of the bodily ferments is stimulated, and leucocytosis is produced. The salts are to be used in the following combination: Sodium chloride 34.4 grams, sodium carbonate 10.13 grams, sodium phosphate 1.1 grams, calcium phosphate 1.23 grams, magnesium phosphate 0.9 gram, potassium carbonate 2.6 grams, boiled water 120 c.c. The sodium chloride, sodium carbonate, and potassium carbonate are dissolved in boiling water, the solution is filtered, and the other ingredients are then added. Of this mixture there is administered to the patient 8 c.c. or a dessertspoonful in a tumblerful of water every three hours. The mixture is to be well shaken before being used. I have employed this treatment with good results in two cases. The first patient was a druggist 45 years old who was suffering from pulmonary tuberculosis. There were tubercle bacilli in his sputum. His pulse was 112, his temperature 101.4° F., and his blood pressure 90. The mineralization treatment was begun. Two days later his pulse was 90, his temperature was 99° F., and his blood pressure was 125. The following day his pulse was 85, his temperature 98.8°, and his blood pressure 135. On that day no tubercle bacilli were detected in his sputum. The other case was that of a laborer, aged 41 years, who was suffering from pulmonary tuberculosis, associated with diarrhea. Bacilli were found in the sputum. His pulse was 112 and his temperature was 102° F. The mineralization treatment was begun. The pulse and temperature on the succeeding days were as follows: 90 and 100°, 100 and 100°, 90 and 99.8°, 90 and 98.8°, 96 and 99.8°, 100 and 99.8°, 90 and 99.4°, 80 and 98.8°, 80 and 98.8°, and 80 and 98°. I regret that in this case I was unable to take the blood pressure.

Charles F. d'Artois Francis, M.D.

Brooklyn, N. Y.

OUR LONDON LETTER.

(From Our Regular Correspondent)

MEDICAL SOCIETY'S DEBATE ON DIAGNOSIS OF SYPHILIS OF THE NERVOUS SYSTEM—COL. FRENCH'S SECOND HUNTERIAN LECTURE—DANGER POINT OF ANESTHESIA—SLEEPING SICKNESS—INSURANCE BILL—HEALTH OF THE ARMY—G. M. C. ELECTION—OBITUARY.

London, November 24, 1911.

Great expectations were formed of the first debate of the session announced by the Medical Society of London. The subject was the diagnosis of syphilis and parasyphilis of the nervous system, and so many recognized authorities had promised to speak that it was obvious discussion must extend over more than one evening. The opening paper was read by Dr. F. W. Mott to an attentive audience, which fully appreciated it. As pathologist of the county asylums, he was able to collect cases of juvenile general paralysis and tabes dorsalis in which the exciting factors of neurasthenia were absent, but in which there was evidence of congenital syphilis.

These cases have to be differentiated from other diseases affecting the brain, spinal cord, and peripheral nerves, and the importance of this is as great as the difficulty of deciding whether the symptoms are purely functional or prodromal of grave organic disease. An examination of the cerebrospinal fluid will decide. The presence of lymphocytes points to a chronic inflammatory condition, and practically in every case of general paralysis, even in the earliest stages, lymphocytosis occurs.

The average time of onset of parasyphilitic affections after infection is ten years, very seldom under five, whereas the converse is the case with syphilis of the central nervous system, most occurring in the first few years, and diminishing with each succeeding year. The onset, course, and progress of the common disease are pretty well known and regular, though subject to remissions, but the parasyphilitic symptoms are insidious and slowly progressive, except in some cases of general paralysis. The pupil and squint phenomena are common, but the Argyll-Robertson pupil is extremely rare in syphilis. In parasyphilis pupil phenomena and strabismus are common, the Argyll-Robertson pupil is rarely absent, especially in tabes and taboparalysis. Dr. Mott insisted on the importance of the last affection, as tabetics are apt to suffer from mental depression, and may resort to alcohol, and to relieve pain acquire the morphine habit. Neither the Wassermann nor lymphocyte test helps, as both tabes and taboparalysis give the reaction, but in his experience Dr. Mott found abundant lymphocytosis, and marked, positive Wassermann pointed to widespread disease, and therefore to involvement of the brain. If, in addition, apoplectiform, migrainous, or epileptiform seizures without gross paralysis had occurred, especially if the knee jerk were absent on

one side and present on the other, he held taboparalysis to be indicated. The importance of the differential diagnosis of the two states cannot be overestimated as to prognosis and treatment, syphilis yielding often in a marvelous manner, but not parasyphilis. The most important subject of differential diagnosis was considered to be between (1) tabes, (2) pseudotabes, and (3) ataxic-toxic peripheral neuritis. Of these the chief points were summarized in tabular form by Dr. Mott, and thrown upon the screen.

Sir David Ferrier recognized as parasyphilis tabetic affections, whether spinal (locomotor ataxia), or cerebral (general paralysis), or cerebrospinal, and every day strengthened the evidence that, whatever else might cooperate, syphilis (hereditary or acquired) was the *sine qua non* in the causation. In the incipient stage diagnosis was sometimes so difficult that every help was welcome. If he specified one symptom as above all characteristic it would be the Argyll Robertson pupil, or reflex iridoplegia in one or both eyes. Practically that was pathognomonic, for exceptions were so rare as to be negligible. When reflex iridoplegia was doubtful other indications of tabes must be marked. Occasionally all symptoms might be so equivocal that they welcomed recent biochemical and cytological methods. He added a distinction he had taught for years in his clinic between general paralysis and cerebral syphilis: in the latter pain could always be elicited by deep pressure, though the patient had made no complaint of spontaneous headache. This was never the case with a general paralytic.

Dr. Savage confirmed the last-named point, and mentioned that long ago he had taught it, though Sir Batty Tuke had said he was wrong. In his large clinical experience he found a marked difference between tabes and tabetic insanity; one was rapidly fatal, the other lasted many years. He thought in general paralysis of the insane there was marked arterial degeneration, causing starvation of the higher centers and the neurons. But in other degenerations (chronic alcoholism and arterial fibrosis) the symptoms of tabes or general paralysis did not appear, so he felt there must be a specific infection. General paralytics slept very well except in the stage of maniacal excitement, but parasyphilitics and cerebral syphilitics almost always slept badly. Another point too little noticed was that general paralytics would retain memory, but alcoholics and parasyphilitics rapidly lost it for recent events. He related a case in which he made a differentiation on the complete loss of recent memory. It was the case of a doctor who had made his own diagnosis of general paralysis, and thanked Dr. Savage for coming, as he left the room. Returning immediately, the patient said: "When did I see you last? You have not been here for a long time." So he assured the patient he had not general paralysis.

The discussion was adjourned.

In his second Hunterian lecture Major French passed on to the treatment of syphilis. As to salvarsan, he had observed Dr. Levy-Bing's work in Paris, who admitted it did not ever abort the disease in the primary stage, but he said in some instances it had produced a negative Wassermann more quickly than mercury, and it rapidly became positive again. At Malta Colonel French had some hectine sent for trial, but the measures he had adopted previously had effectually stamped out the disease, and he had no primary case on which to try the hectine among the 7,000 troops under his care. Iodide of potassium was said by Dr. Hallopeau to exert a decided influence on the sore, but that had been observed many years ago. Like salvarsan, it is a good cicatrizing agent, and removes induration, but that is not cure. Nor have the claims put forward for arylarsenates been substantiated. Relapses were very unusual in Malta, where mercury was employed in the primary and early secondary stage, and later, for military convenience, injections of grey oil for out-patients. In forming an opinion on the relative value of drugs the lecturer held that each must be tried alone, and judged on its own merits.

Now the advocates of salvarsan have not been content to do this, as the literature shows; though proposed to take the place of mercury, it has later been recommended as an adjuvant. The same has happened to other proposed substitutes. A second rule laid down by Major French was that the early manifestations must be removed in four to six weeks, and glandular enlargements, when they exist, must be rapidly reduced in three months. Mercury can do this. Hunter wrote in 1786: "If there is such a thing as a specific, mercury is one for the venereal disease, . . . yet mankind are in pursuit of others, as if specifics were more common than disease." Amplifying this, the lecturer said we must consider before adopting substitutes that the effects of the disease are different with the intensity of infection, personal and racial susceptibility, intemperate habits, neglect of early treatment, and the injudicious use of mercury. There is no class of disease in which judicious early treatment is as beneficial. Major French pointed out the conditions in which the main remedy and the various adjuvants are of most value, and concluded with some remarks on prophylaxis.

Drs. Buckmaster and B. Gardner have read a paper at the Royal Society describing a series of experiments from which they conclude that the direct action of chloroform on the red corpuscles during anesthesia interferes with the oxygen-carrying power. They claimed that the usual initial effect of chloroform diminishes the average depth of respiration, while the rate is very much less affected. The cessation of respiration they regard as an initial danger point, and it is a direct effect of deep and rapid respiration prior to administering the drug, and the higher the percentage of this the greater the danger. But this can be rendered negligible by a low percentage. They hold that some trace of an initial danger is rarely absent.

Yesterday the Colonial Secretary received a deputation in reference to sleeping sickness in Nyassaland, and the relation of the tsetse fly and game to each other. He said, so far as taking every possible step for preventing extension of this disease, they were preaching to the converted. But two commissions were at work, and they were asking him to prejudge the results of these investigators. He would not hesitate to act when he got any definite proof of what was really necessary.

The committee stage of the insurance bill has been concluded under the guillotine. How this is being abused you will see in the fact that one-half of the first part, dealing with sickness, has not been discussed at all. Nineteen old clauses and nineteen new were forced through by the gag. Even government amendments were simply put from the chair and voted on without a word. And this is

called parliamentary government! A number of meetings of medical men have been held in different parts of the country, the majority being branches of the British Medical Association, and they as a rule maintain the six points urged by the executive.

The representatives held their great meeting yesterday, and after prolonged discussion arrived at the same decision.

The bill is provoking widespread and growing opposition by various classes who are affected by it, but the government seems determined only to give way in some directions referred to the report stage. A cabinet minister in a public speech actually remarked that if it did not work well it could be amended every two or three years, as experience might require!

The Army Medical Report for 1910 shows that the improvement in the health of the troops noted in 1909 continues, and it is satisfactory to find that the ratios at home and abroad are the lowest on record, with the single exception of "invalids finally discharged." The ratio for deaths was 3.44, lower by 0.66 per 1,000 than the previous year. The average sick time (9.15 days) to each soldier was last year 1.24 days less than in 1909. The admissions for alcoholism were 46 less last year.

Drs. H. W. L. Browne, T. J. Verrall, and H. A. Latimer are the three successful candidates in the election for representatives on the General Medical Council. So the British Medical Association officials have again monopolized the representation.

Dr. Wilfred Webb, who was formerly in the Indian Medical Service, where he attained the rank of major, died on the 18th inst., aged fifty-three. He qualified in 1878-80, took M.B., C.M., with highest honors, at Aberdeen in 1881, and proceeded to M.D. in 1894. He had been curator of the National History Museum at Netley. In India he had been superintendent of jails, dispensaries, etc. He wrote a "Manual of Vaccination in Hindu," 1886; "The Indian Medical Service: Guide for Candidates and Junior Officers," 1890, and other works, besides contributions to the *Indian Medical Gazette*, the *Lancet*, and the *Practitioner*.

OUR LETTER FROM PARIS.

(From Our Regular Correspondent.)

THE FRENCH SURGICAL CONGRESS—DIAGNOSIS AND TREATMENT OF CHRONIC APPENDICITIS—TREATMENT OF ACUTE PERITONITIS—THE OPEN TREATMENT OF SIMPLE FRACTURES—OBITUARY.

PARIS, October 30, 1911.

THE annual meeting of the French Congress of Surgery opened October 2, 1911, with Prof. Segond as president, who in his inaugural discourse spoke of medico-surgical collaboration. The first question treated of was the diagnosis and treatment of chronic appendicitis, the readers of papers being Walther of Paris, and Silhol of Marseilles. In chronic appendicitis operation is not urgent; medical treatment may always be instituted and prolonged for a certain length of time. Medical treatment should above all consist of absolute rest, prevention of taking cold, and observance of a severe diet. Intestinal antiseptics should be made use of, but their use should not be too prolonged. Massage should be absolutely rejected in cases in which appendicitis is well established. The indications for surgical treatment differ with each case; in appendicitis with relapse and repeated crises appendectomy is necessary; after a single acute crisis the indication for operation is subordinate to conditions dependent on age, condition of life, and profession. With reference to operative technique it is absolutely necessary not to end the operation with removal of the diseased appendix, but always in all cases a wide exploration should be made methodically of all the organs in the neighborhood of the cecum, colon, and omentum. The operative results are excellent. Out of 1,463 cases treated Walther has had ten deaths. As to the therapeutic results it is only after observation for at least six months of the influence of a rigorous regime that a marked modification of the intestinal condition is to be observed.

The second question to occupy the attention of the congress was the treatment of acute peritonitis. The readers of papers were Hartmann of Paris, and Temoin of Bourges. According to Hartmann the results obtained in the treatment of acute peritonitis have been considerably improved in the last few years; but this improvement can only be obtained by an early operation following a precise diagnosis. In the treatment of acute peritonitis it is not sufficient to attempt a cleansing of all the peritoneal cavity, but especially to arouse the curative properties of the peritoneum itself, which possesses means of defense that are very real, and it is sufficient to disembarrass it of its infectious contents, provided that the greater part of these contents have been removed, and to prevent new inoculations by suppressing the cause. The operation should be performed rapidly and simply. It should be destined to destroy the initial focus with the least possible disorder. In most cases it is well to put in place a drainage tube in the depths of Douglas' cul-de-sac, and to keep the patient in a half-sitting position. According to Temoin there is no medical treatment for peritonitis. Only operation is useful and it should be above all early to prevent generalization, and rapid to limit to the minimum intraperitoneal maneuvers. It is necessary above all to destroy the first cause of the peritonitis and to leave out extensive washing and brushing of the intestine. The surgical treatment of peritonitis is one of the triumphs of modern surgery. It has rendered curable an affection which up to now may be said to have been murderous.

The third question of interest was the open treatment of closed fractures. Writers of papers were Alglave of Paris, and Bérard of Lyons. Alglave has studied the operative technique of the open treatment of recent closed fractures. To obtain reduction and maintenance in position of fractures several methods have been devised. The first consists in reduction through an opening and retention in position by double, direct and indirect means, by ligature of the bones, or circling the bones, or by suture of the bones properly considered, or by bolting them together, or by sheathing the fragments, or with clasps. Other simple and direct methods of retention of the fragments after reduction permit us to begin mobilization of the neighboring joints at an early date and prevention of the stiffness which may result. These are simple screwing of the bones, or screwing with metallic plates, or metallic prothesis; lastly, screwing with external splints. These last means of retention should be absolutely aseptic at the moment of their introduction and placed in an aseptic field. If these two conditions are not observed accidents of great importance may take place around the foreign bodies and necessitate their extraction. Another

method consists in reduction by opening the field of fracture, and retention simple and indirect by a plaster apparatus. Lastly, one method attempts to obtain reduction without opening the field of fracture by practising continuous, direct extension by spiking the bones and realizing the retention of the bones in place by means of the extension. In conclusion, Alglave is convinced that the method which assures a toilet openly, the perfect reduction and retention of the fragments in place, while respecting the free play of the articulations, is that which should merit all the votes of physicians in the treatment of fractures which allow a surgical intervention.

Bérard of Lyons has studied the results and indications for open treatment of closed recent fracture of the limbs. Lambotte of Anvers insists on the necessity of a perfect technique over which the fundamental rules of surgery have sway. Above all it is necessary to restore as far as possible the natural contour of the bones and then mobilize as rapidly as possible the articulations, utilizing a very rigorous asepsis. We must make use of good and well-tried materials. Under these conditions operations on fractures are benign, and accidents cannot be attributed to faults of technique.

Vincent Griffon, physician to the Paris Hospitals, physician in chief of the prison of La Santé, has just died, a victim of professonal duty, from an infectious lesion contracted from one of his patients. Griffon was hardly forty years of age. He was one of the youngest physicians of the Paris Hospitals. He was above all occupied by clinical work, pathological anatomy, and microbiology; he was in charge of the laboratory of microbiology of the Faculty of Medicine of Paris. His teaching, precise, simple, and essentially practical, assured him a true popularity with his pupils. In the course of his career he had the rare fortune to know only triumphs without bitterness and rancor. This is a striking contrast to see a life so favored by destiny brutally destroyed in a few hours by a slight professional accident.

Colon Bacillus Infections.—By R. C. Kemp. (See MEDICAL RECORD, December 2, 1911, page 1147.)

Operative Treatment of Fractures.—F. B. Lund believes that in the future when an *x*-ray examination shows that a recent fracture of a long bone is badly overlapped, or in poor position, or that the ends of the bone are presumably separated by soft parts, one will cut down upon them and reduce them by operative methods, provided the patients are in hospitals where the aseptic technique is good, and where the surgeon has taken the pains to master the details of the not inconsiderable operation of the application of plates and screws to these fractures. In case the ends will spring together to stay without plates and screws, the latter need not be used, but the use of plates and screws very much simplifies the putting on of the retentive apparatus. The author also believes that as a result of this treatment the ultimate results in fractures will be considerably improved. The danger of infection is not sufficient to deter one from attempting operation in fractures which are benefited by it. If the results in old, ununited fractures are fairly satisfactory, they will be much better in fresh fractures which could not be reduced satisfactorily.

Relationship of Fibroids to Sterility.—E. B. Young and J. T. Williams, from the study of their statistics and those found in the literature, draw the following conclusions: (1) The percentage of primary sterility among married women with fibroids (about 31 per cent.) is greater than the average for other women (about 10 per cent.). (2) Women with fibroid tumors of the uterus bear fewer children on the average than women with normal uteri. (3) Patients with myomata, on the average, cease childbearing earlier than others. (4) As a corollary to conclusions 2 and 3, it appears that there is a secondary sterility in certain instances, which results from the development of a fibroid in a patient who has previously borne children. (5) Although sterility is more common in women who have fibroids, these tumors do not always prevent conception or even repeated pregnancies. (6) The exact manner in which fibroids produce sterility remains undetermined. (7) Miscarriage occurs in 44.7 per cent. of the cases where conception does take place.

Prolapse of Uterus.—S. Rushmore has devised an operation for dealing with some of the more difficult cases of prolapse of the uterus. The operation presents no new features except the combination of procedures. It consists of three steps: interposition of the uterus, perineorrhaphy and ventrofixation of the uterine cervix.

Some Points of Personal Hygiene That Are Generally Neglected by the American People. I. W. Brewer.

Preventive Medicine.—Dr. H. Bergey states that in the future the ideal of preventive medicine will consist of the following phases of activity: (1) The limitation, or prevention, of the dissemination of the germs of disease by confining the infected persons in such a way as to prevent access to them, of those who are not immune to the disease, or as in malaria, yellow fever, and some other diseases, the prevention of access to the patient of the insect carriers of the specific organism. (2) The destruction of the specific organisms outside of the body, either with chemical substances or physical agents which are destructive to the germs of disease. (3) The use of immune sera to fortify the individual against infection by supplying the specific antibodies to assist the natural defensive powers in overcoming the invading organisms as fast as these gain access to the body. (4) The injection of vaccines, in the form of dead or living attenuated organisms, to bring about the development of specific antibodies in the individual. (5) The use of chemotherapeutic agents to aid the body in overcoming the infective organisms as fast as they gain access to it. (6) The employment of chemical substances, or physical and biological agencies, in the purification of water, milk, and sewage.

Serous Cyst of the Kidney.—R. S. Fowler reports a case of the condition in a woman aged fifty-three years, who had suffered from pain in the back, more marked in the left side, and when changing from one position to another. The diagnosis was made of movable left kidney with tumor. At operation examination of the specimen showed the following: A kidney two-thirds the normal size with anomalous blood vessels and with a cyst occupy-

ing part of the lower third and part of the middle third of the kidney and in relation to, but not communicating with, the renal pelvis. The cyst content was clear serous fluid with very few blood cells, a trace of albumin, but no trace of urea. The author reviews the cases reported in the literature.

Sexual Inversion.—A. Flint reports the case of a male aged twenty-one years in whom all the physical characters were distinctly masculine, and whose external genitals were well developed. The voice, however, was that of a woman. There was absolute sexual anesthesia.

Joint Infections.—C. Ogilvy states that the infection of joints is almost always secondary to a primary infection by an invading organism elsewhere in the body. The infectious organism may or may not be found in the joint. The toxins of the organism alone are frequently responsible for the inflammatory reaction in the joint. The most important factor in diagnosis is to determine the source of infection, and for this reason a previous history of infectious disease should be carefully inquired into. A tuberculous joint abscess is intrinsically a cold abscess. The first step in the treatment is to aspirate. If the process continues unchecked after repeated aspirations and in spite of mechanical treatment, and the abscess begins to point, one should open it, irrigate it thoroughly with a 1 in 4,000 bichloride solution, and sew up the incised wound with two layers of sutures. If more radical surgical measures are demanded one should do an erasion. Upon the foci of disease carbolic acid, followed by alcohol, should be applied. One should never excise the joint in childhood unless as a last resort to save the limb. In adults, on the other hand, an excision of the joint is the best operative procedure, especially in protracted cases of two or more years' duration.

Salvarsan.—J. L. Boehm states that the intravenous method of administering this drug is the only safe method. A single dose of salvarsan will not cure syphilis; it produces only a mild parasitotropic effect.

The Senile Climacteric.—I. L. Nascher states that the normal cycle of life falls naturally into three periods: Development, maturity, and decline, each of about thirty years' duration, and each broken by a crisis about the middle of the period. The period of maturity is broken about the middle of the period by the menopause in the female, and the critical period described by Seré in the male. Analogous to this is the crisis during the period of decline. In many cases there are profound changes in the organism during the early part or middle of the eighth decade; during this climacteric there is a readjustment in the relation between the functions and changes in the organs necessary to carry out the new functional relations. Usually there is mental depression, with some impairment of the faculties and lessened activity and degeneration of some organs and tissues, due to arteriosclerosis or primary degeneration, while other organs and tissues show little change.

Carcinoma of Bone.—R. H. Boggs concludes that carcinoma of bone is not as rare as is generally supposed, and it is of clinical interest in connection with lumbago, rheumatism, etc. It has even been stated that metastasis into the bone is frequently the first evidence of a prostatic tumor.

Treatment of Varicose Ulcers.—A. Gills presents the following method of treating these ulcers: The patient is kept in bed until the swelling has subsided; well directed massage is employed, and the bowels are kept open. At first one should stimulate the granulations with nitrate of silver, thirty grains to the ounce; about three applications are all that are necessary. The ulcer should be protected by sterile gauze and long adhesive straps should be applied to the dry skin on either side until the skin wrinkles well. Fluid will be seen oozing from the ulcer by this squeezing process for several days. It is preferable to have the foot elevated upon two pillows until it has returned to its normal size. Adhesive straps used in this fashion occasion some pain the first few days. They should be changed upon alternate days or oftener.

Personal Hygiene.—I. W. Brewer refers to the following points in personal hygiene that are generally neglected: Failure to wash the hands before meals; the careless cleansing of the teeth; the wearing of gloves and outer garments that are not washable, and an insufficient toilet of the anal region after defecation.

Safety of Surgical Operations.—By G. W. Crile. (See MEDICAL RECORD, July 1, 1911, page 51.)

Balantidium Coli.—F. B. Bowman states that it is not known whether a break or abrasion in the mucosa of the intestine is necessary for the entrance of the *Balantidium coli,* whether it can force its way through the lining membrane by purely mechanical means, or whether a cytolytic ferment is liberated. Once it has entered, its progress is limited only by the length of the colon. The *Balantidium coli* is a parasite which, though not so widespread as the ameba, in individual cases is equally serious in its effects. It does not live in the intestine in a state of harmless commensalism, but causes a dysentery which in its late stages is not amenable to medication and usually results in death.

Cataract Operations.—D. W. Greene emphasizes the importance of thorough preparation of the patient for the cataract operation. The patient should be free from bowel and bladder trouble, cough, dyspnea, dacryocystitis, chronic nasal disease, blepharitis, chalazia, and styes. He should be in a hospital from twent-four to forty-eight hours before the operation, or long enough to allow the attendant to make an estimate of the physical condition, to unload the bowels, to examine the urine, to test the intraocular pressure with the tonometer, to note the bloodpressure and the condition of the arteries, and if bloodpressure is high, e. g., above 220 mm., to reduce it if possible below 190.

Choice of Anesthetic.—A. D. Bevan states that for routine work, ether, by the open method, is the safest and most satisfactory anesthetic and, in the usual run of cases in a hospital service, the anesthetic of choice, in from 75 to 80 per cent. of the cases. Chloroform must be discarded as a routine anesthetic. It produces too many immediate and late deaths to warrant its general employment. It is only in the exceptional cases, as possibly in a laryngectomy in which one might feel that the direct introduction of chloroform vapor into the trachea might produce sufficiently less irritation to the tracheal mucosa with less risk of pneumonia than ether, that one would be warranted in emplying it. Nitrous oxide is the anesthetic of choice for short operations, manipulations, and examinations. It is also the anesthetic of choice in operations on patients with seriously impaired kidneys and often on patients in extremely bad condition, as in typhoid perforations, general peritonitis, etc. It should not be employed in patients with bad hearts. It is not as satisfactory an anesthetic as ether and should not be employed in preference to ether in patients who are good surgical risks.

Care of Advanced Tuberculosis.—W. C. White enumerates the following points in connection with this subject: (1) Provision must be made for all social and racial classes; (2) Provision must be made in general hospitals for a group of cases, mainly for its educational value on doctors, nurses, and the public. (3) Provision must be made for a second large group of cases in State, municipal, and charitable institutions. (4) Provision must be made in special institutions provided by the State, by the municipality, by charity, and by the private means for a third group. (5) Provision must be made for a final group by instruction and care in the homes by doctors and nurses. (6) Small institutional units are of more value than large institutions. (7) All cases must be registered in the health department of the State. The State should supervise and control the whole movement. It should do this through its local agencies and subdivisions (municipalities and counties) and should make certain demands from charitable and other agencies for uniformity of plan and apportionment of work.

Blood Pressure in Pneumonia.—By A. Lambert. (See Medical Record, July 8, 1911, page 93.)

Chronic Hypertension.—L. G. Visscher states that chronic hypertension is more prevalent in the cities than in the country and decidedly more frequent in the middle and well-to-do classes. It is especially the result of continuous brain work, together with overstimulation by coffee, nicotine, alcohol, and other indulgences. Among the toxins causing hypertension the purin bodies stand high. It is necessary to alter the diet list, to reduce the acidosis, and provide alkalies freely in various ways. Hand in hand with manometric examination should go the determination of urea, indican and the acid-titer of the urine, in order to determine the proteid tolerance. It is necessary that the intraabdominal pressure should be slightly positive, but when in excess the diaphragm is pushed upward, the venous inflow from the extremities is obstructed and a rise of blood-pressure in the arteries is caused by the compression if the heart is strong. There are slight dyspnea, moderate hypertension, aching limbs, torpid liver and catarrhal gastritis. The causes of high intraabdominal pressure give the indications for its treatment. The caloric value of the food must be kept up in the regulated diet, which should be adapted to the conditions of the individual stomach. If the patients are lean one may have to overfeed them and one may do harm in too active measures for the reduction of obesity. A reasonable amount of exercise, with warm bathing followed by cold sponging are among the measures recommended. People with a hypertension should eat light evening meals with ease thereafter for a few hours and with a moderate amount of physical exercise, a warm bath, perhaps a warm enema and sleep in a warm bed with the windows wide open.

Leucocytosis in Experimental Measles.—L. Hektoen and H. E. Eggers find that in the monkey the leucocytes behave much as they do in human measles. Preceded by a more or less distinct leucocytosis, there occurs a leucopenia of variable degree corresponding in a general way to the latter part of the preeruptive and the early part of the eruptive period. As to the question whether the leucopenia may not be the result of the injection of foreign blood and connected with the resulting processes of antibody formation and sensitization, the authors state that, while further observations are necessary to settle this point, it may be said that in monkeys injected with human blood for other purposes and in still larger quantities they have noticed either no leucopenia or a transient, very slight diminution in the count. Hence it is concluded that the leucopenia observed in two or three of the experiments represents a reaction to the measles virus.

Eosinophilia of Bronchial Asthma.—W. W. Herrick reports a case of bronchial asthma in which the eosinophile count was at one time as high as 77 per cent. He states that it is questionable if any practical conclusion can be drawn from the blood-picture of bronchial asthma aside from its real value in differential diagnosis. The type of the disease showing eosinophilia is that responding most often to potassium iodide. A thorough trial of this drug is apparently indicated in such cases.

Hematuria Relieved by Nephropexy.—J. B. Squier reports a case of this condition in a woman aged 38 years, who had constant pain over the right kidney, with bloody and excessively painful urination. After thorough urinary and bladder examination a tentative diagnosis of severe hemorrhagic cystitis was made and treatment was instituted, but without relief. Cystoscopy was performed and a small ulceration was found just below the left ureteral opening. The functional capacities of the kidneys was rather puzzling, the findings being largely negative as to disease. There was only a faint trace of albumin in the urine. Operation was thought advisable and the right kidney was exposed and found to be very freely movable, and was brought out of the incision without difficulty. An incision of the kidney was made, splitting it open from pole to pole, revealing no evidence of disease. The ureters were found to be normal. The kidney was sutured together, replaced and anchored by a few chromic gut sutures and the wound was closed except for a small drain at its lower angle. The prospect of relief was considered poor, but the results developed were unexpected. At the end of eight hours the patient passed urine without pain and with but a small amount of blood, and at the end of twenty-four hours the urinary function was practically normal. The convalescence was rapid and recovery seemed to be complete.

The Parasite of Cancer.—By Sir Henry Butlin. (See page 1229.)

Medical Aspects of Some Social Questions.—G. A. Gibson discusses the following subjects: the National Insurance Bill, immigration, eugenics, physical development, and the instillation of sound ideas into children.

Treatment of Cleft Palate.—R. W. Murray describes the evolution of the operative treatment of cleft palate. Langenbeck's operation is the one which he performs.

Evolution of Modern Gynecology.—A. E. Giles reviews this subject, particularly with reference to ovariotomy, extrauterine pregnancy, the surgery of inflammatory disease of the tubes and hysterectomy for fibroids.

Metastatic Suppurative Cyclitis.—Sir William Collins reports a case of this condition in a woman fifty-four years of age. The sequence of events appeared to be a pyemic condition arising from an abscess in the right side of the neck, not very acute in its character and containing watery pus, possibly of old tuberculous gland origin. Thence absorption appears to have taken place with metastatic cyclitis, which became the dominant feature of the illness, metastatic abscesses in the left arm, and a threatened synovitis of the left knee. The lungs, however, did not give any evidence of a breaking down lesion. A diagnosis of iridocyclitis having been made, the right eye was abscissed and eviscerated. The patient recovered.

Ureteral Grafts.—A. Chiasserini performed a series of experiments on the ureter of dogs with vascular grafts. He made use sometimes of pieces of vein (external jugu-

lar, femoral, and saphenous), and sometimes of the carotid artery. He reached the ureter by the extraperitoneal route and sutured the two ends of the ureter to the transplanted vessel by Carrel's method, having first cut away a piece of ureter somewhat shorter than the graft. In 12 cases the continuity between the two ureteral ends was re-established, but a stenosis or a complete occlusion corresponding to the vascular graft was the usual result. The conclusions that the author came to are as follows: There is a possibility of the vessel introduced between the two ureteral ends becoming firmly united to them. The piece transplanted, a few days after the operation becomes shortened so as to draw the two ureteral ends nearer together. The graft becomes thicker and hard, while the lumen is nearly obliterated. The stenosis causes a stoppage in the flow of the urine with consecutive dilatation of the canal of the ureter and hydronephrosis.

Tricuspid Regurgitation.—R. O. Moon reports a case of this condition occurring in a boy aged five years and revealed by autopsy. The mitral valve was normal. On the tricuspid valve there were recent translucent vegetations. The following interesting points are noted in connection with this case: The fact that the systolic murmur was plainly heard at the back is generally held to be against the purely tricuspid origin of it; an accentuated pulmonary second sound seemed to point to the mitral lesion, but in children one cannot attach much importance to these signs. On the other hand, there was no cough or dyspnea, and the comparative absence of edema from the lungs was in striking contrast to the general anasarca. A cantering sound in the tricuspid area which usually points to an abnormal blood pressure in the right ventricle ought, perhaps, to have given the clue to a correct diagnosis.

Bacterial Infection of the Stomach Wall.—F. K. Cahill reports a case in which this condition was diagnosed in a man aged 48 years. The sole complaint was a persistent four breath. The nose and teeth were normal. Streptococci and colon bacilli were discovered in the stomach contents. Autogenous vaccines prepared from these organisms were administered in four doses at intervals of one week, and effected a cure.

A Note on Sprengel's Deformity. A. Mitchell.

Syphilis and Parasyphilis of the Nervous System.—By F. W. Mott. (See page 1193.)

Cholera at Palermo.—L. Rogers spent three weeks at the Palermo Cholera Hospital, where he applied the methods that he had found so successful in the treatment of cholera in Calcutta, India. These methods included the use of intravenous injections of a hypertonic saline solution; and the administration of potassium permanganate by the mouth. By these methods the mortality was reduced to 20 per cent.

Physiological Action of Digalen.—W. L. Symes concludes from his experiments that this drug is an active preparation of digitalis producing characteristic digitalis effects on the circulation and on the secretion of urine.

The Protein Requirement.—W. Tibbles states that the physiological minimum of protein for an adult is 34 grams daily, but the maintenance of life, the prevention of tissue destruction, and the performance of a certain amount of muscular work are possible with an allowance of 50 to 57 grams of protein daily. This is Chittenden's standard. Voit established the rule that a man of average weight requires 119 grams of protein to meet the demands of the body when doing light work. The author believes that Voit's rule should be followed; that protein starvation is the cause of ill health, and that the available evidence of the average consumption in Great Britain of animal protein shows that the consumption of meat in Great Britain is not excessive.

Rheumatoid Arthritis.—F. H. Parker alludes to the intimate connection, at least in certain cases, of this disease with pathological conditions of the nasal mucous membrane, or with carious teeth. Vaccine treatment in addition to measures designed to remove local septic foci has met with a certain amount of success. Attention to the alimentary tract is important; the starches in the diet should be cut down and replaced by milk and fats. Long courses of water drinking are recommended.

Catarrhal Jaundice.—W. J. H. Pinniger reports an epidemic of eight cases of this condition occurring in a children's hospital.

Vomiting in Graves' Disease.—J. A. Nixon notes that this may be controlled by the following procedure: The patient is confined to bed and placed under strict supervision to insure that he does not move hand or foot to supply his own wants; at the same time a substantial and varied diet is administered by mouth.

The Parasite of Cancer.—By Sir Henry Butlin. (See page 1229.)

Nonvalvular Heart Disease.—H. L. McKisack states that the chief causes which damage the heart muscle are either inflammatory changes or degeneration of the muscle fibers. The inflammatory injury is commonly the result of the toxemia of fevers, the chief of which is rheumatism, but familiar examples are seen in pneumonia, measles, scarlet fever, typhoid fever, and other exanthemata. A cloudy swelling of the muscle fiber occurs in almost all pyrexial states, and more definite inflammatory infiltration is common under these circumstances. The degenerations are even more numerous and striking in their effects. Among the commonest is the fatty change caused by an imperfect blood supply to the muscle. This is found to occur in all cases of severe anemia—for example, pernicious anemia, chlorosis, hemorrhage, inanition from improper or insufficient food—and it is one of the factors in the heart muscle weakness of acute rheumatism and other fevers, in which the blood examination usually reveals a marked anemia. Mechanical interference with the proper blood supply to the heart walls is a not infrequent cause of fatty and fibrous degeneration, and occurs in atheroma, thrombosis, or embolism of the coronary arteries. Fibrous changes may occur in the heart muscle analogous to those occurring in the systemic arteries, and probably owing their presence to similar causes—namely, strain, toxemias, especially gout, high tension in the circulation generally, and especially as found in the contracted kidney. This condition of cardiosclerosis is also likely to result from long-continued efforts of a heart, damaged by valve defects, to maintain an efficient circulation, and is the usual form of degeneration which attacks a heart hypertrophied by this or similar causes, and hastens the dilatation and breaking down of compensation under unfavorable circumstances.

Cardiac Failure Treated by Cane Sugar.—A. H. Carter reports a case of heart-muscle degeneration and failure occurring in a lady aged 62 years treated by means of cane sugar administered in doses of 1 to 4 ounces daily. Her improvement began to be obvious after the middle of the second week of this treatment, and by the end of the fifth week it was remarkable. The pulse was steady and stronger, and normally 72 to 78; it was not abnormally altered by exertion, and quickly resumed its normal rate after rest. The first mitral sound was stronger, and altogether of better quality. She could walk nearly 3 miles without a rest or undue fatigue, and a very short rest completely restored her. Her mental vigor was quite reestablished and her feeling of well-being and "fitness" after months of weariness and lassitude was extraordinary.

Enucleation of Tonsils.—S. S. Whillis and F. C. Pybus describe the technique of removing the tonsils by means of the guillotine combined with finger pressure on the anterior pillar of the fauces.

Hypertonic Salines in Infantile Diarrhea.—L. Rogers states that the principle he has introduced in the treatment of cholera, of basing the frequency and amount of saline to be injected on the degree of loss of fluid from the blood as indicated by its specific gravity, has been adapted by him to the treatment of infantile diarrhea.

Control of Bladder after Prostatectomy.—C. Wallace and C. M. Page report a case which seems to indicate that a man can have perfect control of micturition with a patent or patulous internal vesical sphincter.

Elevation of Lower Molar.—F. St. J. Steadman reports a case of accidental displacement of a lower third molar tooth into the tissues of the neck during the operation of elevating this tooth from an abnormal position in the gum.

Sprengel's Deformity.—A. Mitchell reports a case of this rare condition, which is a congenital elevation of the scapula and is defined as "a congenital deformity consisting in an upward elevation of the scapula in its relation to the thorax and to the scapula of the other side."

Berliner klinische Wochenschrift.

November 20, 1911.

Painful Arm Paralysis of Children.—Durlach reports three cases of this injury in very young children. The etiology is sometimes palpable and sometimes obscure. As the three cases were seen within a single week the affection is evidently of common occurrence. The arm hangs limp at the side and readily simulates infantile spinal paralysis, and the latter affection is also at times painful. A fracture might be suggested to the observer, but may readily be excluded. The French style the lesion internal or interior derangement of the forearm, for supination is either avoided or performed imperfectly. While the affection is traumatic it is often very difficult to localize the precise seat of the injury, which is to be conceived of as a slight slipping of the cartilage, probably often spontaneously replaced by muscular tension. Of great significance is the belief of some surgeons that an injury has not taken place in fact, but only in imagination. The pain may be undoubtedly severe enough to cause inaction in the affected limb, and the association of pain with paralysis at least suggests psychogenous methods of treatment. However, with correction of any deformity and proper psychic management the subsequent histories of the case show considerable variation. One child had his condition disappear wholly after a few minutes of consultation. Whether the maneuver employed really reduces a dislocation when one is present seems to be a matter of doubt. In another case mechanical reposition seemed to have taken place, but the child could not move the arm at first and only did so after a stratagem. In the third case, in which there was no sign of displacement, the arm continued to hang limp despite all treatment.

Treatment of Gout with Radium Emanations.—Gudzent has treated a number of cases of gout and chronic arthritis with radium and appears to believe that the latter is a true curative treatment for the metabolic disturbances which constitute the disease. Uric acid in the tissues is rendered soluble and destroyed, an antiphlogistic action is exerted, tissue enzymes are activated, and even the uric acid disappears from the blood. Emanations are of value also in myalgias. The author and his colleagues find the use of radium by inhalation the best method and give 4 or 5 Mache units for every liter of air as the proper dosage. A technique for examination of blood for uric acid is naturally an essential feature of the management. The author mentions a paradoxic case in which the blood was cleansed from uric acid, but the patient nevertheless suffered from an attack of traumatic gout. The term gouty reaction is used to denote a paroxysm of disease in one subject to it who is at the time under treatment. This should be an indication to add colchicum to the treatment. Since a purin free diet cannot expel the uric acid from the blood, the author would not subject the patient to the hardships of one, but would simply order a common-sense regimen. A purin poor diet is of course rational.

The Emanation Action of Mesothorium.—Both Bickel and Emsmann have articles on this subject, radium and thorium being used for comparison. Modern physicists speak of the radium family and the thorium family, referring to the various intermediary products formed from each. While some members have a very short life only a few days or even hours, the so-called radium D is believed to live for many years, while radium F (polonium) remains active for some months. While thorium has a life of over 4 years, mesothorium I has one of nearly 8 years and radiothorium about 3 years. The action of thorium emanation closely resembles that of radium emanation. It is evident that no other radioactive substance can be compared to radium itself, which is believed to have a life of nearly 3000 years. Radium exerts its effects immediately, while from thorium many by-products are first produced. The status gradium substitutes as medicinal agencies has evidently not advanced much beyond the experimental stage.

Buccal, Pharyngeal, and Laryngeal Lesions of Heredosyphilis in the Tertiary Stage.—Gaucher presents a study of the various tertiary lesions, mucous and gummatous, of hereditary syphilis. The mucous syphilides may be superficial mucous patches or gummatous deposits and may be found about the mouth, anus, etc. They often rest on a papule and correspond to mucous tubercles. They are similar to those seen in acquired syphilis. Mucous patches belong especially to the secondary stage, but appear also as tertiary lesions. The oldest patient seen with these lesions by the author in the tertiary period was twelve years of age. Many cases are detailed. Gummata are seen on the lips, cheeks, tongue, pharynx, tonsils, pillars and palate. The gummata after a time soften and leave an ulceration with destruction of tissue. Lingual gummata do not differ from those of acquired syphilis. In the vault of the palate they always ulcerate through and make an opening between the nose and mouth. Such perforations are always due to syphilis. The palate appears swollen, but there is no pain present; it becomes immobile and the vowels cannot be pronounced. After perforation has occurred there is nasal voice. In the larynx we find cicatrices, fibrous retractions, and diminution of the calibre due to secondary lesions that have healed. Tertiary lesions of the larynx accompany those of the pharynx and nose. There are ulcerations of the epiglottis and involvement of the vocal cords. The symptoms are hoarse voice, dyspnea and attacks of suffocation.—*Le Progrès Médical.*

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

PERSONAL HISTORY.

Diseases of the Genito-Urinary System—Degenerative changes in the kidneys are responsible for a mortality which is exceeded only by that due to pathological conditions of the blood vessels and heart, both of these classes of diseases having superseded tuberculosis, which at one time occupied first place in the list. It may be added that this reversal has been brought about less by the extermination of tuberculosis than by an increase in the death rate due to degenerative changes occasioned by the greater stress of modern business methods, by the extension of social pleasures into the late hours when physical and mental rest are so much needed and by the excessive eating and drinking which so often accompanies the accession of financial means.

It is highly important, then, for the examiner to cross question the applicant closely whenever there is a history of one or more of those conditions which, though not necessarily fatal in themselves, may provoke the permanent and dangerous changes to which the tissues of the kidneys are particularly susceptible on account of the present mode of living.

Diseases of the Kidneys—A history of the chronic affections of these organs will rarely be elicited from an applicant for life insurance. A previous occurrence of acute Bright's disease is, however, admitted at times and will lead to postponement until it is certain that a return of the trouble will not take place and all after effects have disappeared. A careful examination of the urine will be resorted to before final acceptance of the risk.

Albuminuria—When there is a history of albuminuria, even though there were no indications of involvement of the kidneys, the examiner will be expected to make an urinalysis of several specimens voided on different days and at different hours, preferably the morning, noon and evening urine of these days. It is advisable to have the applicant sign a statement that he has not been under treatment or on restricted diet for this disorder for at least six months. If these measures are not adopted, permanent or frequent recurring albuminuria cannot be excluded.

Movable Kidney—When there is a history of sickening or dragging pains in the abdomen, especially in women, the possibility of the presence of a floating kidney should be borne in mind. These cases are not acceptable unless the kidneys have been successfully fixed and time enough has elapsed to discover if the organs will remain in place.

Renal Colic—Give the number of attacks and the date of the last one, and ascertain if gravel or a stone passed from the urethra at the time. The term gravel should not be used to describe the precipitation of urates and uric acid sometimes occurring after the urine has become cool and which is of no importance even though it has often been the chief support for a diagnosis of "uric acid diathesis." The examiner will usually be requested to send a specimen of urine to the home office for microscopical examination, as the presence of red and white blood cells is occasionally demonstrated for a long time after an attack of renal colic, a possible indication that some damage to the tissues still exists or another stone is present.

The general opinion in regard to these cases is that they may be accepted when at least six months have elapsed since the last attack, provided there have not been too many recurrences and the microscopical examination of the urine is satisfactory. This view is apt to be modified, however, if the applicant is over forty years of age or an overweight, as in either event a longer period of postponement is advisable.

Hematuria—Give the dates, number of attacks and cause, and state whether there was accompanying pain, colic or passage of a renal calculus. It should be also made plain whether the blood appeared in the urine during an attack of malaria, as this condition is still common in some parts of the country.

Pelvis of the Kidney, Ureter, Bladder—Purulent inflammation of these parts is apt to travel up into the kidneys, and an inquiry should be instituted with this possibility in mind whenever there is a history of such a condition.

Prostate Gland—A good many death claims are paid where the kidneys have become involved through the disturbances set up by enlarged prostates. Hypertrophy of the prostate to a limited extent may exist for a long time without producing marked symptoms, and for this reason the condition rarely comes to the notice of the physician until it has reached a more or less advanced stage. The examiner may well bear this fact in mind when the applicant is over fifty years of age.

Stricture of the Urethra—Complete information should be furnished when there is a history of urethral stricture, especially as to whether there has been any indication of involvement of the kidneys. When sounds have been used, the date of cure should be mentioned as well as the size of the largest sound which the urethra would admit. In mentioning the size of the sound, state whether the French, American or English scale is referred to.

Always question the applicant as to whether he has had any frequent or difficult urination and, if there is any such history, endeavor to find out if it was caused by organic changes in the urethra, prostate, or kidneys.

Hydrocele—When there is a history of this condition it should be included in the report. Give dates of all tappings or operations and of any recurrence.

Association of Life Insurance Presidents.—The fifth annual meeting of this association was held at the Hotel Astor, New York City, on Wednesday and Thursday, December 13 and 14, 1911, under the chairmanship of John R. Hegeman, Esq.

Diabetes and Accidents.—Erfurth says that there are two forms of diabetes occurring after accident: one begins immediately or very soon after injury, the other develops gradually and slowly. The first form of diabetes can be brought in connection with the injury much easier than the second. Injuries of the head, inhalation of illuminating gas, concussion of the whole body, injuries of the digestive tract and digestive glands, injuries from frost or excessive heat, burns, etc., may all cause an immediate appearance of sugar in the urine. This form of diabetes is often of light character, the sugar either altogether disappearing from the urine or only appearing there at intervals. To make it probable that accident had much to do with the second type of diabetes, several of the following conditions should be fulfilled: (1) The accident must be of such nature as is capable of resulting in this disease. (2) In the interval between trauma and the full manifestation of disease there should have occurred

symptoms or signs of developing diabetes. (3) Some disease of the brain or spinal cord or some nervous functional disorder, caused by the accident, should precede diabetes. (4) The interval between trauma and the appearance of diabetes should not be over two years, and during this interval nothing should have occurred favoring the development of the disease.

This late form of traumatic diabetes usually ends fatally within a short time, ranging from three months to five years. Alimentary glycosuria may be its early symptom. If it can be proved that diabetes existed before the occurrence of injury, it may be claimed that the accident has had an untoward effect upon the disease. To support such a claim it must be shown that the amount of sugar excreted has increased; that the type of the disease has become more severe; that acetone and diacetic acid have appeared in the urine; that wounds due to the injury have run a very unfavorable course because of the existing diabetes. The author communicates the details of two illustrative cases.—*Monatsschrift für Unfallheilkunde*, No. 1, 1911.

Lumbago and Accident Insurance.—E. Patry says that in claims for indemnity for accident lumbago leads to greatest differences of opinion between the claimant and the insurance company. From the medical standpoint, there occur unquestionable cases of traumatic lumbago, just as many cases can be traced to a preexisting rheumatism. Quite a number, however, are indeterminable, so far as cause is concerned, and it were better for physicians to state this fact in any such case than take one or the other side of the controversy on insufficient grounds. Patry has collected over 1,500 cases of lumbago among indemnity claims and gives the following differential diagnostic points: Constancy of pain, so far as site is concerned, speaks for trauma rather than rheumatism. Traumatic lumbago usually makes the patient incapable of continuing work immediately after the injury has occurred; if the applicant has continued work for from two hours to several days after injury, then rheumatism or muscular fatigue are the probable etiology. The burden lifted during the onset of lumbago and the manner of lifting it may likewise point to the importance of injury rather than of disease. It must be remembered that lumbago is most easily simulated. The effect of the salicylates gives some points in differential diagnosis, but, of course, therapeutic results cannot be used as deciding arguments; nontraumatic lumbago is frequently not affected by remedies. The duration of lumbago is of importance: an anatomic lesion, such as probably occurs in all cases of traumatic lumbago, can hardly be expected to heal sufficiently to allow resumption of work in a few days. Patry, therefore, does not believe in the traumatic nature of a lumbago if work is resumed within one week of the injury. Unilateral pain is, of course, of some significance. The applicant's age is important; rheumatic lumbago is rare before the age of twenty years, and if indemnity is asked for by an applicant of this age, traumatic lumbago is most probable. In conclusion, Patry repeats that the neutral ground is often the only one to take for a physician who wants to be honest both to the applicant and to the insurance company.—*Korrespondenzblatt für Schweizer Arzte*, No. 22, 1911.

Insurance of Applicants Over Fifty Years of Age.—Van der Heide says that a definite judgment in regard to this question cannot as yet be pronounced. The material on hand shows, however, that while the results of insuring persons over fifty years of age are, of course, not as favorable as with younger applicants, yet the difference is not so great as to make it advisable to refuse such applicants altogether. In order to establish the expectation of life in such persons careful examination of the esophagus, of the rectum, and of the urethra is necessary. Difficulties in swallowing, in micturition, and in defecation, vertigo, and dyspnea must be carefully inquired into. The anamnesis should include a full history of longevity of the applicant's antecedents. The general elements entering into the question of preservation of the resisting power of the individual must be judged. A history of cancer and of apoplexy in the family must be especially inquired into.—*Third International Congress of Insurance Physicians.*

Notes on Life Insurance Examination.—I. Lytle Moore of Toledo, Ohio, points out that medical literature is sadly deficient in material on life insurance examination and that the average man thinks that it requires very little skill in diagnosis to be an efficient examiner. The question of life insurance examination is considered from the standpoint of the physician and the methods to be employed are briefly sketched. Special care is needed to examine those coming from other localities, for bad risks are prone to seek a physician who does not know them. Age, of course, is an important consideration, and the matter must be entered into thoroughly. Occupation is perhaps the most essential point and must be carefully dealt with. Nationality should also be paid due attention. Weight and height and chest and abdominal measurements all have a potent bearing on the question in hand. In the big bellied flabby individuals, who are given to heavy eating and indolent ways, we look for signs of nephritic and arterial degeneration. Thin people are often long-lived; but we must be on the lookout for evidences of tuberculosis. The physician should make certain that the applicant has been vaccinated. Lastly, the physician should be especially scrupulous in ascertaining whether an applicant is addicted to alcohol or any drug habit. Family history as to these points should be also inquired into and every effort made to clear up most features in this connection. Both the alcoholic and the drug taker are given to evasion and in the case of the drug taker the physician is thrown upon his own ingenuity.—*American Medical Compend*, October, 1911.

Influence of Occupation Upon Susceptibility to Diseases Resulting from "Catching Cold."—J. Zamaral as the result of extensive statistical studies reaches the following conclusions: Occupations in which an individual is exposed to continued cold do not cause any tendency to catching cold and its sequences; while occupations that are followed in confined places are associated with a greater morbidity in this respect. Work that is carried on under conditions of alternating intense heat and cold does not favor this morbidity, which shows that the human being has the power of adapting himself without injury to extensive losses of heat. The limit beyond which the action of a low temperature disturbs the normal functions of the body is outside the boundaries of any clinically operative cold-producing factors. If the temperature falls below the former limit, then refrigeration occurs but not "catching cold."—*Casopis lékaru ceskych*, 1911, Nos. 10-17.

Average Length of Life of the German People.—From the death rates which give the number of deaths per 1,000 births at the end of the first, second, third, etc., year of life, the length of life, that is, the whole number of years that these 1,000 persons have lived, is obtained; this sum divided by 1,000 gives the average length of life for the individual. This number is called the average length of life. From the three published mortality tables for the entire German people, the following average life duration can be calculated: From 1871 to 1880, for men, 35.58 years; for women, 38.45; from 1881 to 1890, for men, 37.17; for women, 40.25; from 1891 to 1900, for men, 40.56; for women, 43.97. The average for men has risen 5 years in the last 20 years, that for women 5½ years. Still Germany is behind many other European countries. In Sweden the average length of life is about 10 years higher than in Germany, in Belgium and the Netherlands about 5 years, and in France and England about 4 years. The chief reason for this difference lies in the considerable infant mortality of Germany.—*Journal American Medical Association.*

Book Reviews.

A Textbook of Pathology. With a final section on post-mortem examinations and the methods of preserving and examining diseased tissues. By Francis Delafield, M.D., LL.D., Emeritus Professor of the Practice of Medicine, College of Physicians and Surgeons, Columbia University, New York, and T. Mitchell Prudden, M.D., LL.D., Emeritus Professor of Pathology, College of Physicians and Surgeons, Columbia University, New York. Ninth Edition. With thirteen full-page plates and six hundred and eighty-seven illustrations in the text, in black and colors. Price $5.50. New York: William Wood and Company, 1911.

The well-known textbook of Delafield and Prudden has become in its ninth edition a stately volume of over 1100 pages, with a wealth of illustrative photographs, line drawings, diagrams, colored plates, etc. The authors, or rather the author—for Dr. Delafield no longer participates in revising the book—have kept to the classic consideration of pathology, beginning with the simplest type of inflammation as an introduction to the general processes exhibited by the animal organisms in disease. These processes are treated as much as possible as the reaction of the organism to injury, a phenomenon of adaptation to changed conditions of life, comparable to other manifestations of energy of the living organisms. The student accordingly learns to look upon pathology as the study of living, though diseased, tissues and not merely of dead autopsy material.

A study of infections follows, the bacterial and protozoan excitants of disease, their biological characteristics, and the reaction their invasion of the body calls forth being tersely but freely described. Extremely suggestive chapters on the general problems of immunity precede this section. Tumors and the diseases of blood and blood-forming organs are next considered, Dr. Francis Carter Wood being credited with revision of these sections. A very conservative statement of the results of tumor research, which is "raging" everywhere nowadays, is included. The second half of the book is given up to special pathology, all the newer additions to our knowledge in this field being duly noted. Photographic illustrations are especially fine in this section of the book. The final chapters give the necessary directions for conducting post-mortem examinations and for preparing material for gross and microscopical study.

The revisions and additions of the new edition keep the book among the foremost textbooks on pathology in the English language. It should be a constant companion of the student in his study of medical and surgical affections, for it correlates the clinic and the autopsy room. To the practising physician it should act as a substitute for pathological and laboratory material, the immediate study of which he may be denied by the exigencies of a busy life.

The Physician's Visiting List for 1912. Price, for 25 patients per week, $1.25. Philadelphia: P. Blakiston's Son & Co.

This well known physician's diary, first issued sixty-one years ago as "Lindsay Blakiston's Visiting List," appears promptly in the form familiar to several generations of users. In addition to blank leaves for record of visits, memoranda, addresses of patients, obstetric and vaccination engagements, etc., it contains printed matter on incompatibilities, antidotes, treatment of asphyxia, and a dose table. The book is of good paper, well bound in soft leather, with tuck and pocket.

Der Gynäkologische Operationskursus an der Leiche (Gynecological Operations on the Cadaver). In sixteen lectures. By Dr. Wilhelm Liepmann, Privat Docent for Obstetrics and Gynecology in the Friedrich Wilhelm's University of Berlin. With 387 illustrations, mostly in color. Price 22 Marks. Berlin: Aug. Hirschwald, 1911.

This interesting book was written by the author of a similar work on obstetrical technique recently published, and is of the same general character. The material is presented in the form of clinical lectures illustrated by a series of excellent drawings and photographs of the immediate specimens under discussion. The author divides his subject matter into two parts, the first dealing with operations through the abdominal route, the second through the vaginal. Preliminary to this is an excellent chapter on the subject of lumbar puncture which he discusses in great detail, including experimental procedures on the cadaver, the anatomy of the area involved, and also the technique. It is to be regretted that no recognition has been given to the American workers in the field of spinal anesthesia. A brief review of the contents of the book will probably afford the most satisfactory idea of its scope.

The first few lectures are devoted to the subject of the abdominal corrective operations. The Alexander-Adams procedure is discussed in very minute detail and not only are the various steps carefully presented but a discussion is appended regarding the pathology of the operation. The text at this point is considerably burdened with technical details which might better be considered in a general chapter and, considering the loss of favor which this operation has undergone, it would appear that really too much attention is extended to the same, as the author finally admits that the round ligaments are unimportant in the normal suspension of the uterus. In a succeeding lecture the general subject of laparotomy is considered, after which the operation of ventral fixation of the uterus is taken up in its various modifications, preference being given to the procedure advocated by Bumm. Operations on the tube are next considered, including the subject of extrauterine pregnancy and tubal sterilization. The ovaries and uterus are then considered, followed by a chapter on the bladder, ureter, and kidney. Intestinal operations, including hernia and appendectomy, are also taken up. The second part of the book is devoted to the vaginal operations, which are very fully and satisfactorily discussed and illustrated. The final portion of the book is devoted to a description of a variety of obstetrical operations on the cadaver, including pubiotomy, cesarean section, the operations on pelvic veins, etc. Just why these should have been introduced in a gynecological manual is not apparent except as a means of referring to the author's previous book on the subject of operative obstetrics. Special attention is given by the author to bacteriology and pathology in their bearing on surgical technique and the possible sources of error in operative procedures are also fully recognized.

A final word of comment on the make-up of the book must not be omitted, as in both printing and illustration it represents the highest development of the printer's and illustrator's art. The plates are largely original works by Margaret Wendland, who has most satisfactorily combined her artistic execution with a definite knowledge of anatomy.

A Textbook of Materia Medica for Nurses, Including Therapeutics and Toxicology. By George P. Paul, M.D., Town Health Officer, Round Lake, N. Y.; Sometime Visiting Physician to the Samaritan Hospital at Troy, N. Y. Second Edition, thoroughly revised. Price $1.50. Philadelphia and London: W. B. Saunders Company, 1911.

In this revision the author has done well in not making any addition to the already rather liberal list of drugs and preparations. The new part, which only increases the size of the book by forty pages, contains sections on bacterial vaccines, vaccine therapy, tuberculin in diagnosis, therapeutics in childhood and infancy, massage, electrotherapeutics, and a table of doses. The book is a useful one and should prove popular with nurses. We would suggest that in a subsequent edition the author make his terminology and some of his doses a little more in accordance with those given in the U. S. P. For example, he gives the salts of the alkaloids as hydrobromate, hydrochlorate, instead of hydrobromide, and hydrochloride; and his dose of the tincture of aconite is 1 to 3 minims, as against the 10 minims of the pharmacopœia. These are small matters, but are of more importance in a book for nurses than they would be in a work intended for physicians, as the latter may be presumed to have some knowledge of the subject.

The Coming of Evolution. The Story of a Great Revolution in Science. By John W. Judd, C.B., LL.D., F.R.S., Formerly Professor of Geology and Dean of the Royal College of Science. Price 40 cents. New York: G. P. Putnam's Sons, 1911.

This is the first volume of the Cambridge Manuals of Science and Literature, which consist of a series of small volumes dealing with various aspects of thought, and with the results of recent discoveries, in a form acceptable to educated readers. It is quite fitting that the first volume should have been devoted to the subject of evolution, and should have been written by one who enjoyed the friendship of Huxley, Hooker, Scrope, Wallace, Lyell, and Darwin. This book is a most interesting narrative of the intellectual movement that dominated scientific thought during the second half of the nineteenth century.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON MEDICINE.

Stated Meeting, Held November 21, 1911.

Dr. W. L. Niles, Chairman pro tem.

The evening was devoted to contributions from the medical service of Montefiore Home.

An Unusual Case of Cirrhosis of the Liver.—Dr. Richard Weil presented this patient. There was nothing of interest in the family history. There was no history of any diathesis. The man was perfectly well until about twelve years before his admission to the hospital. At about the age of thirty-four years he developed ascites which was very considerable. He was tapped at Bellevue Hospital, but in a short time the fluid reaccumulated. The fluid removed was a clear serous one. The patient had had syphilis. The tendency toward ascites gradually disappeared and coincident with this there was developed an accessory surface circulation. There were then no further symptoms until five years ago when he had an attack of bleeding from the stomach lasting several days. He had not bled since. Aside from this there were no symptoms at all of any cirrhosis of the liver. There was no bleeding from the rectum. The man came to Montefiore Home for an entirely different condition, with cough, expectoration, loss of weight, and strength, showing a possible pulmonary condition of a low grade. Tubercle bacilli were never found in his sputum. The present status of the patient showed a liver that reached from the normal level above down to a hand's breadth below the free border of the ribs. Its surface was hard and nodular. The spleen was enlarged. There was no fluid demonstrable in the peritoneal cavity. Over the surface of his body there were marked venous plexuses; the accessory circulation was extremely well marked. There were no evidences of any internal anastomoses. The gastric contents, the stools, and the blood count were normal. With regard to the diagnosis of this case, Dr. Weil said that it did not appear to be anything except a portal obstruction. The case was of particular interest because it showed a cure of the cirrhosis of the liver. It had once been said that cirrhosis of the liver could never be cured. Here was the evidence to the contrary.

A Discussion of the Pathogenesis of Hypertrophic Pulmonary Osteoarthropathy, with a Report of Four Cases.—Dr. Harlow Brooks read this paper. He said said that search of the text books and "Systems of Medicine" showed that in by far the larger number this condition was not mentioned and one might be led to the conclusion that either the condition was unimportant or that it was exceedingly rare. This last statement was disproven by the fact that Theodore Janeway had reported a series of 93 cases collected during the year 1903. Hypertrophic pulmonary osteoarthropathy had frequently been confused with acromegalia. Some doubt still existed as to the precise lesions present in pulmonary osteoarthropathy. The enlargement of the hands and feet must be distinguished from the mere clubbing of the fingers and toes such as was seen in simple congestive states as, for example, in congenital or long standing cardiac lesions, for actual enlargement of the hands and feet was an essential feature of the disease. Post-mortem or radiographic examination of the distal ends of the long bones showed an ossifying periostitis. Most of the studies recently published with radiographic observations put stress on this as the essential lesion, but stated that thickening or exostoses of the ends of the bones of the leg and arm were not present. Some of the observers described changes in the face and skull. Facial changes were present in all of the four cases that came under his observation, and Dr. Brooks was of the opinion that they were an essential finding. After relating the history of his four cases, describing the pathological findings in three of them, and comparing these with the cases reported in the literature, Dr. Brooks concluded that the chief lesion characteristic of the disease under discussion was an ossifying periostitis with, in many instances, actual bone growth limited almost exclusively to the distal diaphyses of the long bones of the legs, arms, hands, and feet. Lesions in the carpal and tarsal bones were not, as a rule, marked, neither did they find the formation of osteophytes present on the terminal phalanges as was supposed to be the case before the routine employment of the *x*-ray. The facial changes consisted of a thickening over the malar prominences and a subcutaneous fibrosis which gave to the nose a globular appearance strongly suggestive of the facial changes in acromegalia. This lesion was entirely in keeping with those of the extremities and it was a fairly constant finding in this disease. In a review of the cases reported, one could not help being impressed with the unanimity with which other lesions of a definite primary type were reported. In the 93 instances collected by Janeway, pulmonary lesions were present in 65 cases and but 5 were given in which no apparent primary cause could be ascribed. Marie believed that the condition was a sequel of an inflammatory affection of the lungs or pleura, and that the cause was to be ascribed to the taking up of toxic products from the diseased thoracic foci and a transmission of them to the extremities of the body. The process was, therefore, an infectious, toxic, hypertrophic inflammation. After reviewing the theories that had been advanced to account for the changes characteristic of hypertrophic pulmonary osteoarthropathy, Dr. Brooks had been led to the conclusion that two factors were necessary, comparative youth, and the presence of lesions of the lung, pleura, or heart, most commonly of the lung, as a result of which there was an obstruction to the venous return or deficient pulmonary oxidation. That the changes were not purely the result of septic intoxication was clearly shown by the fact that they did not appear in liver or splenic abscess, in osteomyelitis, chronic dysentery, or those numerous other conditions characterized by prolonged septic absorption, and it seemed probable that infectious processes played rather a minor rôle, although they were present in most reported cases and doubtless where toxins were circulating in the blood venous stasis and fibrous hyperplasia were favored. The three post-mortems reported, as well as the living case in all probability, united all the above mentioned factors as did most published cases.

Dr. George Mannheimer reported the case of a man, fifty-five years old, who came to him complaining of pains in his hands and feet which he attributed to exposure. On careful examination, however, Dr. Mannheimer found the typical picture of hypertrophic pulmonary osteoarthropathy. Not only were the fingers clubbed, but also the phalanges were enlarged, the interphalangeal joints, the wrists, and ankles. The condition reminded one somewhat of acromegaly. But the nails were incurved, the hands were long and thick, and there were no acromegalic changes of the skull. The patient besides presented the characteristic features of cachexia, *e. g.*, emaciation, adynamia, and an unhealthy color of the skin. The examination of the chest revealed a latent pulmonary tuberculosis. There was no fever and no tachycardia, no cough, no sputum. No one would have said from the physical signs alone that there was an active process present in the chest. But the cachexia and the osteoarthropathy were taken to be the manifestations of an insidious intoxication, namely, a slowly progressive form of pulmonary tuberculosis. Three months later the man died from acute phthisis and tuberculosis of the intestines and peritoneum. The case illustrated that pul-

monary osteoartropathy was not dependent on stagnation and putrefaction of pulmonary secretions.

The Orthodiascope in Diagnosis.—Dr. C. Gotlieb said that the object of the orthodiascope was to get a true outline of a viscus, the heart for instance, and this was done by parallel projection. The radiographic plate showed the heart by central projection with its accompanying enlargement and distortion. The enlargement was inversely proportional to the distance between the tube and the patient. The further the tube was from the patient the more accurate would be the outline. Orthodiascopy was a valuable method since neither percussion nor fluoroscopy could give true values. Orthodiagrams could be made in the upright or the prone position. The *x*-ray passed through a small diaphragm, through the patient, and then through the center of a small fluoroscopic screen. The diaphragm, the center spot of the screen, and a marker were all on the same straight line, and with this straight line a viscus was encircled. By pressing an air bulb, the marker was caused to make an imprint on a sheet of paper mounted in the rear of the tube. After the orthodiagram was made accurate measurements must be taken and compared with standards as given by Geödel and others. Due allowances were made for age, height, and weight. As a rapid and accurate diagnostic office method, the instrument was invaluable.

The Phenolsulphonephthalein Test for Renal Function.—Dr. Louis Kristeller presented this paper, in which he stated that the statistics of the New York Board of Health showed that the mortality from Bright's disease had been constantly increasing during the past thirty years. As a cause of death it now ranked next to pneumonia and tuberculosis. The mortality might still be higher as the disease was frequently overlooked, because clinical symptoms and urinary examination were often not sufficient to demonstrate its presence. The older tests for kidney function were cumbersome and inexact and therefore rarely used. The phenolsulphonepthalein test was recommended on the ground of its mathematical exactness and the extreme simplicity of its application. One centimeter of red alkaline solution containing six milligrams of phenolsulphonepthalein was injected into the muscle of the arm or lumbar region. The entire contents of the bladder were collected at the end of one hour and again at the end of the second hour. The quantity of the drug in the two specimens was then determined by colorimetric methods in the laboratory. This drug kept in solution and could be put up in ampules, each containing a sufficient amount for one test. The injection was small, painless, and unaccompanied by irritation. The results were quick and could be frequently repeated without harm to the patient. Dr. Kristeller said that he and Dr. Goodman had published the results of the test on 40 persons, some healthy and others having various nephritic lesions, about one year ago. Since that time they had performed about 50 more tests. Their observations, like those of Geraghty and Rowntree, showed that healthy kidneys eliminated 40 to 60 per cent. of the injected drug in the first hour and from 15 to 25 per cent. in the second hour. When the physiological function of the kidneys was impaired the excreted amounts were diminished. The amount of excretion of the drug had varied during the first hour all the way down to 3 per cent., to traces, and even to entire absence, thus they obtained a mathematical picture of the degree of the derangement. The values were lowest in chronic interstitial and in chronic diffuse nephritis; chronic parenchymatous nephritis gave on several occasions normal amounts, in other cases diminution, probably indicating interstitial involvement. Kidney insufficiency could exist without albumin and casts. These two facts had been substantiated by the tests. Comparative tests in cases where only one kidney was diseased seemed to show that the excretion of phenolsulphonephthalein ran parallel with the capacity of the kidneys to excrete the normal waste products of metabolism. The test was valuable for prognosis. The lower the excretion of the drug the greater was the retention of nitrogenous and probably also of other waste products. They had also made tests that showed the advantages of restricting protein food. This test had been an important help in surgical kidney conditions. It remained to be proven whether it would be of value in eclampsia, syphilis, gout, arteriosclerosis, and perhaps in some skin and nervous diseases.

Dr. Charles Goodman stated that he had used phenolsulphonephthalein for estimating the functional efficiency of the kidneys for a year and a half. His experience in over 100 cases, medical as well as surgical, led him to believe the elimination of phenolsulphonepthalein went hand in hand with the excretion of normal products of metabolism. He also believed the test promised to be the best of those heretofore devised. Dr. Goodman mentioned some of the cases in which the test proved to be more valuable than the clinical data in establishing a diagnosis. A solution of phenolsulphonepthalein possessed the following advantages: (1) The drug did not readily decompose and could be boiled; (2) the dose, 0.1 c.c. of the solution, contained 0.006 gram of the dye; (3) the injection was painless and was not followed by any irritation; (4) the drug was entirely excreted by the kidneys; (5) the drug could be demonstrated in the urine in from 3 to 10 minutes, and from 50 to 70 per cent. was recovered during the first two hours; (6) the drug lent itself to accurate calorimetric measurement.

Massive Tuberculosis of the Liver.—Dr. E. Felberbaum made this report and demonstrated the specimen. The case demonstrated the difficulties of diagnosis; it was first considered to be a case of malignant disease of the stomach and liver; tuberculosis was not even thought of. The microscopical examination revealed the true nature of the condition. The patient was a Russian, fifty-two years of age. His present illness dated back nearly a year when he was suddenly seized with severe abdominal pain which was most severe over the left iliac region. The next day he began to hiccough and this continued for a week. He rapidly lost weight, became very weak, and had to remain in bed. Cramp-like epigastric pains appeared, but lasted only a short time. His chief complaint was pain in the epigastrium and weakness. His present status showed emaciation, a dry skin, a diffused pigmentation, general palpable lymphnodes, abdominal protuberance, a liver much enlarged, and a slight rise of temperature. Some lymphnodes enlarged and suppurated, requiring incision and drainage. Early in December, 1910, he developed a severe cough, a moderate temperature, a cachetic appearance, and abdominal pains, and there was dullness over the right lung posteriorly with râles especially marked at the apex. The examination of the sputum was negative. The heart sounds became very feeble, the respirations quickened, and the abdominal distention greatly increased. Edema followed and the patient finally succumbed. Many retroperitoneal lymphnodes were found to be enlarged. The stomach was found to be normal. The liver was very much enlarged, irregular, and studded throughout with innumerable nodular masses. These were white in color. The right lung was filled with miliary growths. Both lungs and liver contained the tubercle bacilli. There was much caseation. The specimen presented showed a massive tuberculosis of the liver.

Pyloric Obstruction Diagnosed by the Newer Methods and Verified by Operation.—Dr. I. O. Palefoski reported this case. The patient was a woman, twenty-seven years old. Two years ago she was suddenly seized with a severe burning and stabbing abdominal pain, felt very faint, was nauseated, but did not vomit. After five weeks

she felt much improved, but then had a relapse which was followed by emaciation and weakness; she lost about 22 pounds. Occasionally blood was found in the stools which she attributed to hemorrhoids. The patient was observed at two reputable hospitals where her condition was regarded as one of neurasthenia. She was admitted to the Montefiore Home six months ago. She was much emaciated, had tenderness over the right iliac region, and had a moderate leucocytosis; her case was diagnosed as chronic appendicitis, dilated stomach, gastroptosis, and particularly neurasthenia and splanchnic neurosis. In spite of what was done for her she did not improve. It occurred to the doctor that the symptoms she presented might well be explained by a subacute or chronic pyloric or duodenal ulcer. After a careful study of the symptoms he concluded that he had to deal with a case of partial pyloric obstruction. Laparotomy was performed by Dr. Charles Goodman and adhesions were found surrounding the pylorus and anterior wall of the stomach. A gastroenterostomy was performed and the patient was now doing well. He regarded these adhesions as due to a perforation of an old pyloric ulcer. The following points were emphasized: (1) The case amply illustrated the justification of suspecting a diagnosis of "neurasthenia" or "functional disease." (2) Without the aid of the duodenal tube and *x*-ray the recognition of partial pyloric obstruction was next to impossible. (3) To estimate the degree of obstruction both Gross's and Einhorn's duodenal tubes should be used in conjunction. (4) The pain experienced during the passage of the duodenal tube in pyloric obstruction roughly estimated the degree of such an obstruction and the pain might well be termed "labor-like" in character, comparing the capsule of the duodenal tube to the presenting part, the peristalsis of the stomach to the uterine contraction and the pylorus to the pelvis. (5) The duodenal tube in the future would become as useful in recognizing affections of the upper alimentary tract as the stethoscope in cardiac lesions was at present.

Dr. Charles Goodman said that the obstruction of the pylorus was relieved by division of the extreme and dense adhesions about the pylorus. A gastroenterostomy was performed to assure the patient permanent relief, as he feared the adhesions might recur. The patient's symptoms were relieved by the operation.

Treatment of Arthritis Deformans (with Illustrative Improved Cases).—Dr. S. Boorstein said that about eight months ago they had started careful systematic treatment of their arthritic cases and the results were very encouraging. The treatment was divided into (1) that of the general condition and (2) that of the joints. Since infection played an important part in bringing on the disease and aggravating the condition, they first looked for the source of infection: the mouth was examined for carious teeth, pyorrhea alveolaris, diseased tonsils, etc. The digestive tract was carefully attended to and the urine was frequently examined. As a routine measure, each patient received two or three enemata a week and this seemed to greatly relieve the joint pains. The patients ate whatever agreed with them; it was an object to increase the nutrition of the joints and to improve the condition of the atrophied muscles. Milk, cheese, and buttermilk were given in large quantities since it was claimed that the calcium contained therein had a markedly beneficial effect. The patients were kept out of doors as much as possible. Patients were given steam baths three times a week; they were kept in a sitting posture for 10 minutes at a temperature of 200 to 225; the head was covered with a towel wrung out of ice water. This was followed by a spinal douche at a temperature of 90 with a force of 20 pounds. Baking was found to be very useful, producing an immediate and powerful stimulation of the vital body functions and bringing an increase of blood to the part; this was followed by massage. Light baths were used and the benefit was due to promotion of extensive elimination of the products of poor metabolism. Active and passive hyperemia were very useful. Massage, together with exercise, was a very useful part of the treatment. The massage was given only three times a week. This increased the nutrition of the joints and diminished the possibility of ankylosis, muscular atrophy, and contractures. Exercise was found to be the most effective part of the treatment. As yet they had had no occasion to use operative treatment in these cases, although some had advised it. So far as drugs were concerned, they used only occasionally aspirin or tincture of gelsemium to control pain. Special training was given to nurses in order to stimulate their personal interest in this work.

A Case of Arthritis Deformans.—Dr. S. Boorstein presented a man, a teacher by occupation, twenty-seven years old, who had been bedridden for about two years prior to his admission to the hospital. His knees were swollen and contracted to an angle of 45 degrees and there was a great deal of pain in all of his joints. He was unable to dress, undress, or feed himself. After eight months' treatment he was able to walk, although with a brace, and had no pain. He dressed himself, undressed, and shaved now; he could write without discomfort and at present did the clerical work of the department at the Montefiore Home.

Dr. Harlow Brooks said he was sure that one could carry out such a treatment as described by Dr. Boorstein, without even the electrical aid, especially when treating an intelligent patient, and achieve just such results. It seemed to him that it was almost impossible that the man presented, who when first seen seemed crippled for life, should improve so and become a useful member of society.

A Case of Brain Syphilis.—Dr. Albert Polon reported this case. The patient was a female, forty-three years old. She was twice married and her present husband was distinctly syphilitic; she had lived with him eighteen years without conceiving. Eighteen months ago she had projectile vomiting and mental deterioration. She was treated for several months for gastrointestinal trouble. Finally a neurologist saw her when she presented a picture closely resembling that of tumor of the pituitary body. She was operated upon for tumor of the hypophysis cerebri. She was discharged soon after in an improved condition. A few weeks later she developed a complete right ophthalmoplegia and later a complete left hemiplegia. She here presented the rare type of paralysis known as paralysis alternans superior (ophthalmoplegia on one side and hemiplegia on the other). Syphilis of the brain ranked in frequency with tumor of the brain and multiple sclerosis. Among 5,500 cases of nervous affections Nonne diagnosed 85 as lues of the cord and brain; and among 72,000 patients in the general service of Eppendorfer Krankenhaus, 280 were found to be afflicted with lues of the cerebrospinal system. Among 500 cases at the general service of the Montefiore Home, 20 were diagnosed as lues of the central nervous system. The history of syphilis, the clinical picture presented, and the Wassermann findings justified an active antisyphilitic treatment with the result that, within a few days, the ophthalmoplegia completely disappeared, motion returned in the paralyzed leg, and a consensual light reaction could be obtained on the blind eye. The instructive features of the case were as follows: (1) The importance of unearthing the fact of syphilitic infection in any clinical condition, but especially in a neurological affection. (2) No matter how typical a brain condition might appear, the possibility of its being luetic should be borne in mind. (3) Not too much reliance should be placed on the Wassermann reaction. (4) The effectiveness of Ehrlich's "606" in syphilis.

A Case of Complete Heart Block.—Dr. Samuel G. Ehrenreich reported this case. The patient was seventy-one years of age and was admitted to the Home in May, 1908. He was an excessive smoker until a few years ago. There was no history of venereal disease. His wife had borne six normal children and had had no miscarriages. When admitted he complained of dyspnea, moderate cough, slight expectoration and frequent inconstant pains in both axillæ; there was neither hemoptysis nor fever and there were no night sweats. There was a gradually increasing general weakness. An examination revealed a generalized emphysema and an adhesive pleurisy over the right base. A slight blowing murmur was audible at the apex, transmitted to the left. While at the Home nothing was observed that was unusual until six months after admission; then there was noted an irregularity in the heart's action; the pulse rate was 64 per minute during one of his acute pleuritic attacks; the day following the pulse came down to 46 per minute. The heart action was very irregular, the extra-systoles being quite frequent. There was then noticed a pleuritic rub audible over the left base. The bradycardia had persisted up to date, the pulse rate being between 38 and 46 per minute, with occasional exceptions when it rose. The blood pressure had always been between 180 and 220 mm. of mercury. When the bradycardia first appeared, polygraphic tracings were taken by Dr. Felberbaum who immediately diagnosed the condition as one of complete heart block. It was only when the pulse rate increased to 78 or more that a partial heart block was present. The Wassermann reaction was positive and a gumma in the auriculo-ventricular bundle was suspected. The administration of antisyphilitic treatment gave negative effects. The auricles contracted at least twice as often as the ventricles, and there was a complete disassociation of the contractions in the two.

Radiography in Medical Diagnosis, with a Report of Original Observations on the Diaphragm.—Dr. S. Wachsman made this report and demonstration. His object in presenting his plates was to urge coöperation, as much as was possible, between the internist and the radiographer, and also to call especial attention to the diaphragmatic line which offered very interesting features.

Chronic Polyarticular Arthritis: X-Ray Studies, Together with Some Observations Concerning Etiology.—Dr. George R. Elliott read this paper and gave a lantern slide demonstration. He said that not many years ago the arthritic manifestations of so-called acute rheumatism were looked upon as due to a single poison, and one organism after another was singled out only to be set aside. The skill of the diagnostician was still taxed to definitely fix upon the particular organism acting. With chronic polyarticular arthritis they were passing through a similar experience. They were dealing with a composite manifestation. There had been established one fact which had done much to put them on the right track for the solution of the problem, *i. e.*, in all the chronic arthritides they were dealing with a secondary and not a primary process. Quite a number of chronic articular processes had been diagnosticated and in them the first cause was known. They were all more or less familiar with the arthritic manifestations of the gonococcus. To fix upon a definite organism was not always possible. They saw arthritic manifestations complicating, for instance, scarlet fever, typhoid fever, syphilis, etc., where the microorganism could not be found in the joint; yet they knew that the arthritis in some way was due directly to the systemic disease. There was another set of cases which had been clearly differentiated and set aside under the term neuropathic or neurogenetic. Syringomyelia and locomotor ataxia supplied many examples of secondary chronic arthritis of this peculiar type, the arthopathies. Again, there was another class of cases, the arthritis urica type, where between the first deposit of crystals in the cartilage and the extensive resorption and apposition of bone there were found many and varied anatomical joint findings. Few gave trauma its full value as a causative factor in chronic arthritis. Men like Sutton, Lane, Baumler, and Garrod had stamped trauma with much emphasis as a causative factor in these cases. There remained a very large class in which belonged most of the arthritic patients they had under treatment at the Montefiore Home, the chronic progressive rheumatism of the French, or the rheumatoid arthritis of the English, and much had been written seeking to prove a central nerve origin of these cases. Trophic, metabolic, and atrophic were words that were much used, but they still were looking for the first cause. In some of the patients at the Home the primary cause had ceased to exist and the patients were suffering from the end products. The disease had become quiescent, or they were suffering from the vicious circle established, plus the result of intestinal toxic irritation. The majority of the cases, according to the teachings of the French, had no connection with common infections or toxic dyscrasias, but humidity was looked upon as the true etiological factor. They pointed to the great frequency of the disease among the soldiers who were compelled to sleep upon the ground in 1870. Those who did not accept the dampness as a first cause believed that it activated hereditary tendencies. It was shown that among those at the Montefiore Home 40 per cent. either lived in damp rooms, or were exposed to prolonged damp cold and, therefore, they felt safe in concluding that they were dealing with a contributory etiological factor. With regard to the anterior infections in their cases, they sought for possible sources less differentiated and more localized. Particular attention was then given to the tonsils, ears, and gums as foci of origin. They had searched for cardiac lesions, glandular enlargements, suppurative abdominal processes, puerperal sepsis, chronic inflammations of the uterus and adnexa, furunculosis, acne, history of pus anywhere in the body, etc. In spite of the difficulties encountered in getting statements from these patients they were surprised that they had been able to fix upon a relatively large number that gave as the probably first cause an initial infective focus of origin in 52 per cent. Three followed immediately an attack of influenza; 1 began immediately after parturition; 1 two weeks after labor; 1 soon after puerperal sepsis; 1 immediately after the removal of a uterine tumor; 1 after the removal of a tumor of the neck; 1, a patient of seven years, after a prolonged suppurative process; 1 after repeated serious attacks of hemorrhages from hemorrhoids; several after a so-called "cold." With their present knowledge of the subject, and with the causative factor established in a certain number of the cases, Dr. Elliott believed that they were justified in believing that in quite a large number of cases they had located the primary focus of origin. He showed that the *x*-ray enabled them to differentiate a number of external arthritic types. Owing to the composite nature of the arthritic process where complex etiological factors had been active he did not feel that they were yet justified in concluding that the *x*-ray gave them many distinct disease entities.

College of Physicians of Philadelphia.

At a stated meeting, held November 1, Dr. Arthur V. Meigs and Mr. H. L. Marsh presented a communication entitled "The Quantitative Analysis of Human Milk." The work represented observations covering a period of two years, the clinical aspect of the subject being presented by Dr. Meigs and the results of the chemical studies detailed by Mr. Marsh. The findings confirmed, in a general way, those of Dr. Meigs made twenty-nine years ago. They showed that the proteids of cows' milk are about three times as large in amount as those of human

milk. The lactose could never be obtained free, being always in combination with some indeterminate substance. An effort was made to isolate each of the component substances as such. It was pointed that mothers' milk undergoes little qualitative change during the entire period of lactation, and probably it is not necessary to change the strength of milk mixtures for children from one period to another, but rather the amount given at feedings. The discussion of the paper was opened by Dr. John Marshall, who considered the chemical aspects of the subject, and it was continued by Dr. J. P. Crozer Griffith and Dr. Edwin E. Graham, who considered the clinical features.

At this point the president, Dr. George E. de Schweinitz, announced that the college would take a recess for the purpose of permitting the treasurer, Dr. Richard H. Harte, to present a statue of Aesculapius. Dr. Harte gave a brief account of the life and times of the God of Medicine, the son of Apollo, and uncovered the heroic statue, which is a replica of one at the Vatican. The statue was accepted on behalf of the college by Dr. S. Weir Mitchell, who expressed the thanks of the college not alone for this magnificent gift, but also for active and long-continued service as treasurer and in other capacities.

On resumption of the regular scientific business Dr. Joseph Sailer presented a communication entitled "The Cecum Mobile." He pointed out that this condition does not necessarily connote a morbid state, as the mesentery of the cecum exhibits considerable variability in length and mobility. On the other hand, the disorder may give rise to pain in the right iliac ossas, with symptoms of indigestion, and it may be readily mistaken for appendicitis. In fact, in three of the four cases reported by Dr. Sailer operation had been performed for the relief of appendicitis, but the original symptoms persisted after removal of the appendix. Constipation is frequently associated with the affection. The recognition is to be made by palpation, by inflation and by *x*-ray examination after ingestion of emulsion of bismuth. The disorder is relatively common, and may be readily overlooked. Dr. Wm. S. Wadsworth read a paper entitled "The New Relations Between Chemistry and Anatomy." He pointed out the importance of comprehending the chemical composition of the structures of the body, as well as the changes that take place in connection with the various physiological processes.

Philadelphia Neurological Society.

At a stated meeting held October 27 Dr. Tom A. Williams reported cases as follows: (1) "Variable Migrainous Recurrent Paralysis, Followed by Permanent Lateral Homonymous Hemianopsia"; (2) "Recurrent Vertigo from Hypadrenalism Cured by Opotherapy"; (3) "A Case of Hysterical Hyperesthesia Incapacitating Locomotion Cured in One Week by Psychomotor Discipline"; (4) "Barking and Roaring Tic Removed in One Day." Dr. Alfred Gordon demonstrated "A Case Presenting Simultaneously Tic, Facial Spasm, and Choreiform Movements." The patient was a neurotic man who presented habitual, purposive movements of the lips, nose, eyelids, brows, forehead, and hands. Dr. Charles W. Burr reported "A Case of Angioneurotic Edema Cured After the Administration of Salvarsan." The patient was a man, with a definite history of syphilitic infection, in whom swelling of the tongue, at times apparently threatening suffocation, developed from time to time, following the employment therapeutically of mercurials, arsenic, and other medicinal agents. At other times swellings appeared also in other parts of the body. An intravenous injection of arsenobenzol was given for the syphilitic infection, and thereafter there was no further occurrence of the angioneurotic edema. Dr. James Hendrie Lloyd and Dr. L. J. Hammond reported "A Case of Brain-Tumor Successfully Located by Means of the *x*-ray." The patient was a young man, 19 years old, who presented a gait suggestive of cerebellar disease, with weakness on the left side of the body, loss of stereognostic sense in the left hand and exaggeration of the left knee jerk, but without distinctive changes in the eyegrounds or fields of vision. *X*-ray examination showed distinctly a shadow in the right parietal region. Accordingly, a segment of bone was removed from the exceedingly thin calvarium over the site of the supposed new-growth and a considerable amount of fluid was evacuated on puncture. A number of hard tumor-masses were appreciable, but their removal was deferred for a secondary operation. The patient recovered speedily, and he returned to his home. It was not for a number of weeks that he returned on account of intensification of the symptoms. As much as possible of the neoplastic tissue was now removed, but the patient failed to do well, and death resulted in the course of a week. Examination of the tissue removed showed it to have a calcareous consistency and histological examination disclosed the structure of a psammoma. No doubt it was by reason of the peculiar composition of the growth that its presence was demonstrable by the *x*-ray.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

Texas State Board of Medical Examiners.

Austin, June 27-29, 1911.

ANATOMY.

1. Describe the clavicle.
2. Describe the elbow joint.
3. Give origin and insertion of the following muscles: Posterior tibial, flexor carpi radialis.
4. Describe the internal iliac artery; give relations of anterior tibial artery.
5. Describe the vagus nerve.
6. Name and locate the ductless glands.
7. Give relations and nerve supply of kidney.
8. Describe the lower lobe of the left lung.
9. Name the ligaments of the uterus.
10. Briefly describe the common bile duct.

HISTOLOGY.

1. Give the relation of the various constituents of the blood to each other.
2. Give the diagram of a cross-section of the shaft of the humerus. Describe the Haversian system and show the relation of the parts to each other.
3. Give the constituents of bone relative to the organic and inorganic parts.
4. Define cartilage. Define the following cartilages and tell where found: (*a*) Hyaline; (*b*) White; (*c*) Interarticular; (*d*) Connecting; (*e*) Circumferential; (*f*) Stratiform; (*g*) Reticular.
5. Describe striped and unstriped muscle, and name organs in which unstriped is found.
6. Where is the (*a*) Axiscylinder Purkinje? (*b*) White substance of Schwann? (*c*) Neurilemma?
7. What is the relative difference between the sympathetic and cerebrospinal fibers?
8. Name the layers of the skin from within outward.
9. Name the coats of the arteries and give structural difference.

PHYSIOLOGY.

1. Name and classify the principal nerve upon which the function of voice depends.
2. In what three important organs of the body is the existence of vasomotor nerves still an uncertainty?
3. Give function of the gall-bladder; state whether or not the flow of bile into the duodenum, in the normal subject, is continuous and uniform.
4. Give the principal factors controlling the flow of lymph; in what respect does its circulation differ from that of the blood?
5. Give the four principal ways in which heat is regularly lost from the body and the percentage of each.
6. Give definition of a carbohydrate; give four functions of carbohydrate foods.
7. Give specific gravity, chemical reaction, average daily quantity, and constituents of normal urine.

8. Give chief source, average daily quantity excreted, and where formed of urea.
9. As it applies to caisson work and in the therapeutic use of oxygen, give the effect of breathing (*a*) condensed (*b*) rarefied air; give symptoms of increased and decreased percentages of oxygen.
10. Give specific gravity and chemical reaction of gastric juice; name its principal enzymes and give action of each in the process of digestion.

CHEMISTRY.

1. When is an element in what is called the "nascent" state?
2. Define catalysis.
3. Give a brief summary of the "ion" theory.
4. Describe a reliable test for free hydrochloric acid in the stomach contents.
5. Describe "Gmelin's" test for bile in the urine.
6. Describe a practical test for each of the following: (*a*) albumin, (*b*) sugar, (*c*) indican, in suspected urine.
7. Give (*a*) symptoms of poisoning from, (*b*) treatment of same, (*c*) quantity sufficient to cause death, and (*d*) a test of iodine.
8. State (*a*) fatal dose, (*b*) symptoms of poisoning from, and (*c*) a test for cyanide of potassium.
9. Salicylic acid is sometimes used as a preservative. Say how you could detect it in a food or beverage.
10. Give (*a*) symptoms, (*b*) treatment, and (*c*) a test for acetanilid poisoning.

BACTERIOLOGY.

1. Name the organism that causes gonorrhea.
2. What important disease is caused by the Klebs Loeffler bacilli?
3. What is antitoxin? How is diphtheritic antitoxin prepared?
4. Describe the process of staining tubercle bacilli in sputum.
5. Name the most important pus-producing bacteria.
6. What important disease is produced by the *Amœba coli?*
7. What microorganism causes tetanus, and why is it so necessary to open up punctured wounds immediately after the reception of injury?
8. What microorganism is considered the cause of erysipelas?
9. What temperature is required for the growth and cultivation of all disease-producing bacteria?
10. What microorganism causes influenza?

PHYSICAL DIAGNOSIS.

1. Name and describe the physical signs in the three stages of croupous pneumonia.
2. Physical signs of chronic interstitial pneumonia.
3. Physical sign of pneumonokoniosis.
4. Physical signs of cardiac hypertrophy.
5. Physical signs of cardiac dilatation.
6. Physical signs of serofibrinous pleurisy.
7. Physical signs of aortic regurgitation.
8. Physical signs of plastic pericarditis.
9. Give differential diagnosis, from physical signs, of acute dilatation of the heart and pericarditis with effusion.
10. Define and describe amphoric respiration, and state of what condition this breathing is pathognomonic.

PATHOLOGY.

1. Name some of the varieties of degeneration.
2. Name some of the results of endocarditis.
3. Define endarteritis. What are the dangers to the tissues in endarteritis obliterans?
4. Name the blood and glandular changes in lukemia.
5. How would you distinguish between fatty degeneration and fatty infiltration?
6. What two pathological conditions result from altered secretion of the thyroid gland?
7. What do you understand by the union of a wound by first intention?
8. Name the common malignant tumors of the breast.
9. Define the difference between a thrombus and an embolus.
10. What is the pathology of typhoid fever?

OBSTETRICS.

1. Give signs and symptoms of pregnancy.
2. Give symptoms and signs of approaching labor.
3. Name the diseases from which a mother should be carefully protected before and after labor. (*b*) Explain protective measures.
4. Give, in detail, management of a normal labor.
5. Give types of placenta prævia and their treatment.
6. What would you do if the waters were drained off and a hand and foot were found presenting together?
7. (*a*) In case of twins, if the first came feet first, what special care should you take in delivering the head? (*b*) Why?
8. Define puerperal eclampsia. (*b*) Give treatment before, during, and after labor.
9. State how you would manage an infant after its birth. (*b*) What attention should the babe's eyes receive?
10. Give explicitly the treatment of abdominal pregnancy from conception to termination of pregnancy.

GYNECOLOGY.

1. Define ectopic gestation and mention three of the most important diagnostic symptoms of tubal pregnancy.
2. If a tubal pregnancy is diagnosed before rupture, what treatment would you advise? Describe technique of operation for tubal pregnancy.
3. (*a*) Mention three pathological types of endometritis. (*b*) In what class of patients would you suspect that an exciting endometritis was tuberculous, and what steps would you take to confirm the diagnosis?
4. What diagnostic significance would you attach to postmenopause hemorrhage from the uterus?
5. Mention three of the earliest symptoms of cancer of the cervix uteri, and mention three other conditions of the cervix with which it might be confused.
6. Give three clinical symptoms of retroversion of the uterus and indicate treatment.
7. Mention five distinctly diagnostic symptoms of carcinoma of the breast.
8. When should lacerated perinea be repaired, and why? Give a brief reason for your answer to this question.
9. (*a*) What are the clinical symptoms of dysmenorrhea? (*b*) Mention four types of dysmenorrhea.
10. Briefly describe a typical case of chronic pyosalpynx and differentiate it from appendiceal abscess and tubal pregnancy.

SURGERY.

1. How would you manage a fracture of the lower and middle third of the shaft of the femur?
2. Give differential diagnosis of luxation of the hip and fracture of the surgical neck of the femur? Give methods of managements of each.
3. Give indications for gastroenterostomy. Give operative technique.
4. When and why would you advise the drainage of the gall-bladder? Give indications for extirpation of gall-bladder and give operative technique of the extirpation of the gall-bladder.
5. Give differential diagnosis of concussion and compression of the brain. Give indications for trephine. Give operative technique.
6. Give indications for ligation of middle meningeal artery. Give location and operative technique.
7. Give operative technique for acute, non-suppurative appendicitis; acute suppurative appendicitis; acute perforative or gangrenous appendicitis without abscess; acute perforative or gangrenous appendicitis with abscess.
8. Give clinical symptoms of floating or movable kidney and operative technique for nephrorrhaphy.
9. With no union for three months after compound-comminuted fracture below knee, where there were necrosis and suppuration, would you or would you not advise amputation? Why? Give operative technique.
10. Give clinical symptoms of empyema. Give operative technique.

HYGIENE.

1. Explain the difference between contagious and infectious diseases and give examples.
2. What infectious or contagious diseases are communicated through the medium of the air? What through foods? What by insects? What method can you suggest for combating the latter?
3. Explain the presence of hookworm in the body. What do you recommend to lessen the prevalence of the disease?
4. Name five diseases commonly regarded as requiring regulation by quarantine and state the time necessary to maintain same in each case.
5. What methods would you employ to determine the cause of an epidemic of typhoid fever in your community?
6. Given a case of diphtheria to attend, outline in detail what measures you should adopt to protect the community against an epidemic.
7. How would you determine whether drinking water and milk suspected of being unfit for domestic use was safely pure or not? What precautions should be advised pending such decision?

8. Name three reliable fumigation agents and give detail for procedure for the use of one of them following a contagious case.
9. What hygienic measure should be observed in the management of pulmonary tuberculosis?
10. What precautions should be taken to secure and maintain a pure supply of cistern water?

MEDICAL JURISPRUDENCE.

1. Define insanity and give the best classification for legal purposes.
2. What do you understand by "superfetation" and how distinguished from twin pregnancies?
3. Define and give differences between impotence and sterility.
4. What are the elements of responsibility in criminal malpractice, and the relief from such responsibility?
5. How should blood stains be studied? And how would you distinguish the human blood globule from that of other sources?
6. In order to convict for infanticide, give four positive elements of criminality that the law requires.
7. What are the post-mortem signs found in the newborn after asphyxia? After strangulation? After starvation and exposure?
8. Describe death from electricity and give post-mortem appearances. Where does the medicolegal interest come in?
9. Describe in very minute detail an autopsy.
10. Define rape and tell what three conditions are necessary to be produced by medical testimony to prove rape.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

TEXAS STATE BOARD OF MEDICAL EXAMINERS.

Austin, June 27-29, 1911.

ANATOMY.

1. See Cunningham's "Anatomy" (1909), page 181; or Gray's "Anatomy" (1910), page 169.
2. See Cunningham's "Anatomy" (1909), page 279; or Gray's "Anatomy" (1910), page 306.
3. POSTERIOR TIBIAL. *Origin:* Posterior surface of interosseous membrane, outer portion of posterior surface of shaft of tibia, and upper part of internal surface of fibula. *Insertion:* Tubercle of scaphoid, three cuneiforms, cuboid, and second, third, and fourth metatarsal.
FLEXOR CARPI RADIALIS. *Origin:* Inner condyle of humerus, inner margin of oleeranon process of ulna, and upper part of posterior border of ulna. *Insertion:* Pisiform, unciform, and fifth metacarpal.
4. *For internal iliac artery.* See Cunningham's "Anatomy" (1909), page 848; or Gray's "Anatomy" (1910), page 671.
RELATIONS OF ANTERIOR TIBIAL ARTERY. *In front:* Skin, fascia, tibialis anticus, extensor proprius pollicis, extensor longus digitorum, anterior annular ligament, anterior tibial nerve. *Behind:* Interosseous membrane, tibia, and anterior tibiotarsal ligament. *Externally:* Extensor proprius pollicis, extensor longus digitorum, and anterior tibial nerve. *Internally:* Tibialis anticus, and tendon of extensor proprius pollicis.
5. See Cunningham's "Anatomy" (1909), page 600; or Gray's "Anatomy" (1910), page 1006.
6. See Cunningham's "Anatomy" (1910), page 1210; or Gray's "Anatomy" (1910), page 1437.
7. See Cunningham's "Anatomy" (1909), pages 1130, 1133, 1135, and 1140; or Gray's "Anatomy" (1910), pages 1345 and 1356.
8. See Cunningham's "Anatomy" (1909), page 988; or Gray's "Anatomy" (1910), page 1194.
9. *The ligaments of the uterus* are: Two round ligaments, two broad ligaments, anterior or vesicouterine ligament, posterior or rectouterine ligament, two sacrouterine ligaments.
10. See Cunningham's "Anatomy" (1909), page 1120; or Gray's "Anatomy" (1910), page 1334

HISTOLOGY.

1. (1) Red corpuscles, about 5,000,000 to the cubic millimeter. (2) White corpuscles, about 7,000 to 10,000 per cubic millimeter; (of these there are: small mononuclears, about 20 per cent.; large mononuclears, about 8 per cent.; polynuclears, about 70 per cent.; and eosinophiles, about 2 per cent.). (3) Platelets, about 400,000 to the cubic millimeter.
2. See Cunningham's "Anatomy" (1909), page 72; or Gray's "Anatomy" (1910), pages 37 and 39.
3. *Composition of bone* is thus given by Cunningham:

Organic matter (Fat, Collagen)		31.04
Mineral matter:		
Calcic phosphate	58.23	68.97
Calcic carbonate	7.32	
Calcic fluoride	1.41	
Magnesic phosphate	1.32	
Sodic chloride	.69	
		100.00

4. *Cartilage* is a material which is a transition stage of connective tissue into bone. When boiled it yields chondrin. It is not vascular, and is found in adult life chiefly in the joints, in the parietes of the thorax, and in various tubes which are to be kept permanently open.
Hyaline cartilage is composed of round or oval cells and intercellular substance. It is found in embryos in regions where bone is to be formed, also in the nose, larynx, trachea, bronchi, and in symphyses, epiphyses and synchondroses; costal cartilage and epiphyseal cartilage are composed of it.
White cartilage, also called *fibro-cartilage*, is composed of white fibrous tissue and cartilage in varying proportions. It is found at the insertion of the ligamentum teres into the head of the femur, in the intervertebral discs, in the symphysis pubis, and interarticular cartilages.
Interarticular cartilage is found in the temporo-mandibular sterno-clavicular, acromio-clavicular, wrist and knee joints.
Connecting cartilages are found between the bodies of the vertebræ and between the pubic bones.
Circumferential cartilage surrounds the margin of some articular cavities, as cotyloid and glenoid cavities.
Stratiform cartilage forms a thin coating to bony grooves through which muscle tendons glide; also found in tendon of Peroneus longus and of Tibialis posticus.
Reticular cartilage is probably elastic cartilage, found in the epiglottis, external ear, Eustachian tube, and cartilages of larynx.—(From Gray's *Anatomy.*)
5. *Voluntary* muscle is striated, has long narrow fibers with cross striations and many nuclei beneath the sarcolemma. *Involuntary* muscle is non-striated, has spindle-shaped fibers, one nucleus centrally located, and no sarcolemma. The great exception is cardiac muscle, which is involuntary and also striated. *Voluntary muscle* is found in all the skeletal muscles, pharynx, diaphragm, larynx, external ear, and eye. *Involuntary muscle* is found in the alimentary tract from the middle third of the esophagus to the anus, in the ducts of glands, in the trachea and bronchial tubes, within the eyeball, the internal urinary and genital systems, circulatory (except the heart) and lymphatic systems, and the capsules of some organs.
6. *Purkinjè's cells* are found in the cortex of the cerebellum. *White substance of Schwann* is found surrounding the axis cylinder of medullated nerve fibers. *Neurilemma surrounds* the medullary sheath of cerebrospinal nerves and the axis cylinder of sympathetic nerves.
7. *Cerebrospinal nerve fibers* are medullated; and consist of an axis cylinder, a medullary sheath, and a neurilemma. *Sympathetic nerve fibers* are mostly non-medullated; and consist of an axis cylinder and a neurilemma, but have no medullary sheath.
8. See Cunningham's "Anatomy" (1909), page 773; or Gray's "Anatomy" (1910), page 1155.
9. See Cunningham's "Anatomy" (1909), page 781; or Gray's "Anatomy" (1910), page 576.

PHYSIOLOGY.

1. The principal nerve upon which voice depends is the tenth cranial nerve or pneumogastric; it is a mixed nerve.
2. "There are three important organs of the body—namely, the heart, the lungs, and the brain—in which the existence of a vasomotor supply is still a matter of uncertainty."—(Howell.)
3. *The function of the gall-bladder* is: (1) To store up the bile between the time of its secretion and its passage into the duodenum; (2) to eject the bile into the duodenum. Although the bile is formed more or less continuously, it enters the duodenum periodically during the process of digestion.
4. *The principal factors controlling the flow of lymph* are: (1) Intracapillary pressure, which tends to filter the plasma through the endothelial cells composing the walls of the capillaries; (2) the force of diffusion, depending upon the inequality in chemical composition of the blood plasma and the liquid outside the capillaries, or, on the other side, between this liquid and the contents of the tissue elements; (3) the force of osmotic pressure; (4) variation in the permeability of the capillary wall.—(Howell.)

The lymphatic circulation differs from the circulation of the blood in that it (the lymphatic circulation) is only in one direction, namely, toward the heart.

5. *Four principal ways in which heat is lost from the body:*

(1) By urine and feces, 1.8 per cent.
(2) By expired air, 8.7 per cent.
(3) By evaporation from skin, 14.5 per cent.
(4) By radiation and conduction from skin, 73.0 per cent.

6. A *carbohydrate* is an organic substance, formerly of unknown constitution and containing in its molecule 6, or some multiple of 6, atoms of carbon, and hydrogen and oxygen in the proportions to form water.

Four functions of carbohydrate foods: (1) As a source of energy; (2) source of heat; (3) to save tissue waste; (4) to spare or aid the proteids.

7. NORMAL URINE. *Specific gravity:* About 1015 to 1025. *Chemical reaction:* Acid. *Average daily quantity:* About 40 to 50 ounces. *Constituents:* Water; urea, uric acid, hippuric acid, xanthin, hypoxanthin, creatin, creatinin; sulphates, chlorides, and phosphates (of sodium, potassium, etc.), and pigments.

8. The *chief source* of urea is the nitrogenous intake (proteids) of the food; *average daily quantity excreted* is about 500 grains; it is *chiefly formed* in the liver.

9. *Effect of breathing condensed air:* Muscular and articular pains, paralysis, dyspnea, and congestion.

Effect of breathing rarefied air: Headache, vertigo, nausea, weakness.

Symptoms of increased percentage of oxygen: Inflammation of lungs, convulsions, and death.

Symptoms of decreased percentage of oxygen: Dyspnea, convulsions, and anoxemia.

10. GASTRIC JUICE. *Specific gravity*, about 1002 or 1003. *Chemical reaction*, acid. *Principal enzymes:* (1) Pepsin, which converts proteids into proteoses and peptones; and (2) Rennet, or Chymosin, which curdles milk.

CHEMISTRY.

1. An element is said to be in the *nascent state* at the moment that it is set free from one of its compounds.

2. "*Catalysis* is chemical decomposition induced by the presence of a body which either takes no part in the reaction or is restored to its original state at the end of the process."—(Stedman.)

3. The name *"ion"* was first applied by Faraday to the primary products of electrolysis; those which separate at the positive electrode, or anode, are called *anions,* while those which separate at the negative electrode, or cathode, are called *cations.* Thus potassium sulphate yields the cation K and the anion SO_4. Hydrogens, the metals, and basic radicals are cations; hydroxyl and the acid residues are anions. *Ionization*, or dissociation into ions, occurs when an electrolyte is dissolved. A solution of potassium chloride contains not only the molecule KCl but also the cation K and the anion Cl, and the action of the current is to separate these (already liberated) ions at the respective electrodes.—(Witthaus' *Essentials.*)

4. *Test for free hydrochloric acid in gastric contents:* Gunzburg's reagent (phloroglucin 2 grams; vanillin, 1 gram; dissolved in 100 c.c. of alcohol), freshly prepared, and a few drops of filtered gastric contents (equal parts of each) are mixed in a porcelain dish, and then evaporated in a water bath; in the presence of free mineral acids a bright scarlet is produced, beginning at the upper border.

5. *Gmelin's test for bile pigment:* Put 3 c.c. HNO_3 in a test tube, add a piece of wood, and heat until the acid is yellow; cool. When cold, float some of the urine to be tested upon the surface of the acid. A green band is formed at the junction of the liquids, which gradually rises, and is succeeded from below by blue, reddish-violet, and yellow.

6. *Test for albumin:* "The urine must be perfectly clear. If not so, it is to be filtered, and, if this does not render it transparent, it is to be treated with a few drops of magnesia mixture and again filtered.

"The reaction is then observed. If it be acid, the urine is simply heated to near the boiling point. If the urine be neutral or alkaline it is rendered *faintly* acid by the addition of dilute acetic acid, and heated. If albumin be present a coagulum is formed, varying in quantity from a faint cloudiness to entire solidification, according to the quantity of albumin present. The coagulum is not redissolved upon the addition of nitric acid."

Test for sugar: First remove any albumin that may be present, then "render the liquid strongly alkaline by addition of sodium carbonate. Divide about 6 c.c. of the alkaline liquid in two test-tubes. To one test-tube add a very minute quantity of powdered subnitrate of bismuth, to the other as much powdered litharge. Boil the contents of both tubes. The presence of glucose is indicated by a dark or black color of the bismuth powder, the litharge retaining its natural color."

Test for indican in the urine: The urine is mixed with one-fifth its volume of 20 per cent. solution of lead acetate and filtered. The filtrate is mixed with an equal volume of fuming hydrochloric acid containing 3:1,000 of ferric chloride, a few drops of chloroform are added, and the mixture strongly shaken one to two minutes. With normal urine the chloroform remains colorless, or almost so; but if an excess of indoxyl compounds be present the chloroform is colored blue, and the depth of the color is a rough indication of the degree of the excess.—(From Witthaus' *Essentials of Chemistry.*)

7. POISONING BY IODINE. *Symptoms:* Pain in esophagus and stomach, vomiting, diarrhea, severe abdominal pain, mouth pale and dry, odor of iodine on breath, quickened respiration, weak and rapid pulse. *Treatment:* Wash out the stomach with water containing albumin and starch paste or sodium thiosulphate in solution. *Death* has followed ingestion of one dram by an adult and of 20 grains by a child of four years. *Test:* The urine of the patient if agitated with carbon disulphide becomes colored violet by iodine (but not by the iodides).

8. CYANIDE OF POTASSIUM. *Fatal dose:* Death has followed the ingestion of 2 or 3 grains, and persons have recovered after swallowing 30 or 40 grains. *Symptoms of poisoning:* Lips and mouth corroded, burning pain in throat and stomach, vertigo and insensibility, face pale and bloated, convulsions of a tetanic character, quick pulse, slow and stertorous respirations, loss of consciousness. *Test:* Moisten a filter paper with freshly prepared tincture of guaiac, dip this paper into very dilute solution of copper sulphate, and after drying moisten it with a solution containing the suspected substance; a deep blue color results if a cyanide is present.

9. *To detect the presence of salicylic acid:* "It is best detected in solution, and solids and semi-solids should be macerated in water and then strained through a white cotton cloth. Two or three ounces of the fluid to be tested is used, adding to it a few drops of sulphuric acid. Shake thoroughly and filter. To the clear liquid add three or four tablespoonfuls of chloroform, mix by a rotary motion, but do not shake, or an emulsion will be formed which is difficult to break up. Allow the chloroform to settle and remove as much as possible by means of a pipette. This is placed in a test tube with an equal amount of water and a small piece (a little larger than a pin's head) of iron alum. Shake well and allow to settle, and if salicylic acid is present the upper layer will have a purple color."—(Friedenwald and Ruhrah.)

10. *Symptoms of acetanilid poisoning:* Chilliness, cold sweat; nausea; pulse is soft, slow, and feeble; respirations slow and shallow. *Treatment:* Lavage, diffusible stimulants, application of heat, coffee or strychnine, inhalation of oxygen, or saline infusion. *Test:* "The most convenient method is to test for the presence of the drug in the urine. For this purpose the urine is concentrated and boiled for three minutes with about one-tenth of its volume of hydrochloric acid. After cooling it is shaken up with an equal volume of ether, the ether separated and evaporated, the residue dissolved in water, and a few drops of a 5 per cent. solution of phenol added. Some solution of chlorinated lime is now added, and if para-amido-phenol (acetanilid) is present the solution becomes red, and on adding ammonium hydroxide it is changed to blue."—(Riley.)

BACTERIOLOGY.

1. The organism that causes gonorrhea is the gonococcus of Neisser.

2. Diphtheria is caused by the Klebs-Loeffler bacillus.

3. *Antitoxin* is a substance formed in the body, of a protective character, and capable of rendering inert the poisonous products of bacteria.

Diphtheria antitoxin is obtained from the horse, the animal having been rendered artificially immune by repeated injections extending over a period of several months of gradually increasing quantities of the strongest diphtheria toxin. As the bacilli themselves are not injected, the horse does not become infected with diphtheria, but he gradually acquires a tolerance for the toxins of the disease and develops in his blood a substance (antitoxin) which has the power to neutralize those toxins. At the proper time, when it is thought that his blood has acquired the requisite degree of potency, the animal is bled, and the serum—the part of the blood containing the antitoxin—is

carefully separated from the clot, filtered, and standardized. The last procedure is accomplished by determining the quantity of antitoxin serum required to offset the effects of the minimum quantity of toxin necessary to kill a guinea-pig in a definite time. The strength of the antitoxin is measured in units, a unit containing the amount of antitoxin required to save the life of a guinea-pig which has been injected with 100 fatal doses of toxin."—(Stevens' *Materia Medica.*)

4. To demonstrate the existence of *tubercle bacilli* in the sputum: The sputum must be recent, free from particles of food or other foreign matter; select a cheesy-looking nodule and smear it on a slide, making the smear as thin as possible. Then cover it with some carbolfuchsin, and let it steam over a small flame for about two minutes, care being taken thtat it does not boil. Wash it thoroughly in water and then decolorize by immersing it in a solution of any dilute mineral acid for about a minute. Then make a contrast stain with solution of Loeffler's methylene blue for about a minute; wash it again and examine with oil immersion lens. The tubercle bacilli will appear as thin red rods, while all other bacteria will appear blue.

5. *The most important pus producing bacteria* are: *Staphylococcus pyogenes aureus, Staphylococcus pyogenes albus, Staphylococcus pyogenes citrcus, Streptococcus pyogenes;* also sometimes the pneumococcus, gonococcus, *B. coli communis, B. pyocyaneus, B. typhosus,* and *B. epidermidis albus.*

6. Amebic dysentery is caused by the *Amœba coli.*

7. Tetanus is caused by the *Bacillus tetani.*

It is necessary to open up punctured wounds immediately after the injury, on account of the possible presence of the *Bacillus tetani.* This is anerobic, and comes from the soil, and cannot develop in the presence of oxygen.

8. The *Streptococcus erysipelatis* is considered to be the cause of erysipelas.

9. For the growth and cultivation of the disease-producing bacteria there is required a temperature approximating that of the human body.

10. Influenza is supposed to be caused by the *Bacillus influenzæ.*

PHYSICAL DIAGNOSIS.

1. See French's "Practice of Medicine" (1910), page 158; or Osler's "Practice of Medicine" (1909), page 175.

2. See French's "Practice of Medicine" (1910), page 693; or Osler's "Practice of Medicine" (1909), page 630.

3. See French's "Practice of Medicine" (1910), page 694; or Osler's "Practice of Medicine" (1909), page 633.

4. CARDIAC HYPERTROPHY: "*Inspection* reveals fullness or prominence of the precordium with a distinct impulse. *Palpation* detects the impulse one or two intercostal spaces lower down and to the left. It is stronger and more or less diffused—the heaving impulse. *Percussion* determines an increase in the area of cardiac dullness vertically and transversely on the left side of the sternum, unless the right ventricle is also hypertrophied, when the cardiac dullness is increased to the right of the sternum. *Auscultation* in simple hypertrophy without any valvular changes detects a loud first sound of a somewhat metallic quality, the second sound being strongly accentuated. In the presence of valvular disease the characteristic murmurs are heard in addition."—(Hughes' *Practice of Medicine.*)

5. CARDIAC DILATATION: "*Inspection* detects enlargement and distention of the superficial veins and an indistinct, often wavy and diffused, cardiac impulse. If tricuspid regurgitation is present jugular pulsation will be observed. *Palpation* confirms inspection; the impulse is feeble, irregular, and heaving. *Percussion* serves to determine extension of the area of cardiac dullness transversely and especially toward the right side. *Auscultation* in the presence of valvular lesions reveals characteristic murmurs. If there are no valvular lesions the cardiac sounds are weaker than normal and the first sound is sharper in quality than usual."—(Hughes' *Practice of Medicine.*)

6. See French's "Practice of Medicine" (1910), page 708; or Osler's "Practice of Medicine" (1909), page 646.

7. See French's "Practice of Medicine" (1910), page 600; or Osler's "Practice of Medicine" (1909), page 800.

8. See French's "Practice of Medicine" (1910), page 570; or Osler's "Practice of Medicine" (1909), page 777.

9. See French's "Practice of Medicine" (1910), pages 618, 617, and 570.

10. "*Amphoric respiration* is a blowing respiration having a musical or metallic quality. It is a variety of bronchial respiration produced in a large cavity with firm walls, permitting the reflection of the sound. An imitation of this sound, though only an imperfect one, is produced by blowing over the mouth of an empty bottle. The amphoric character is present with both the acts of inspiration and expiration. Amphoric or metallic respiration is indicative of a large cavity, not common in phthisis, but more often heard at the upper part of a lung compressed by fluid air, as in pneumo-hydrothorax."—(Hughes' *Practice of Medicine.*)

PATHOLOGY.

1. *Degenerations* are: Parenchymatous, fatty, amyloid, hyaline, colloid, mucoid.

2. See French's "Practice of Medicine" (1910), pages 578 and 581; or Osler's "Practice of Medicine" (1909), page 787.

3. *Endarteritis* is inflammation of the inner coat of an artery.

The danger to the tissues in endarteritis obliterans is in the interference with the nutrition and subsequent degenerative changes.

4. See French's "Practice of Medicine" (1910), pages 526, 529, and 530; or Osler's "Practice of Medicine" (1909), pages 732 and 735.

5. In *fatty degeneration* the cell protoplasm is converted into fat; in *fatty infiltration* there is a deposit of fat within the cell, or in the intercellular tissues.

6. Two pathological conditions resulting from altered secretion of the thyroid gland: Myxedema, and exophthalmic goiter.

7. See Rose and Carless' "Surgery" (1908), page 252; or Da Costa's "Surgery" (1908), page 110.

8. *Common malignant tumors of the breast:* Carcinoma, sarcoma, and epithelioma.

9. A *thrombus* is a clot in the blood-vessels during life. An *embolus* is an intravascular obstruction from the lodgment of a foreign body.

10. See French's "Practice of Medicine" (1910), page 70; or Osler's "Practice of Medicine" (1909), page 65.

OBSTETRICS.

1. *Positive signs of pregnancy:* (1) Hearing the fetal heart sound; (2) active movement of the fetus; (3) ballottement; (4) outlining the fetus in whole or part by palpation; and (5) the umbilical or funic souffle.

Doubtful signs of pregnancy: (1) Progressive enlargement of the uterus; (2) Hegar's sign; (3) Braxton Hick's sign; (4) uterine murmur; (5) cessation of menstruation; (6) changes in the breasts; (7) discoloration of the vagina and cervix; (8) pigmentation and striæ; (9) morning sickness.

Subjective signs of pregnancy, in the order of their appearance, are: Cessation of menstruation, morning sickness, increased frequency of urination, active fetal movements.

Objective signs of pregnancy, in the order of their appearance, are: Softening of the cervix, changes in the mammary glands, discoloration of the vulva and vagina, pulsation in the vaginal vault, Hegar's sign, active fetal movements, ballottement, palpation of the fetus, intermittent uterine contractions, hearing the fetal heartbeat, rate of growth of the uterine tumor.

2. *Signs of approaching labor:* Dilatation of the os, characteristic recurrent pains, and the escape of blood-stained mucus from the cervix ("the show").

3. See Williams' "Obstetrics" (1909), pages 480, etc.; or Hirst's "Obstetrics" (1909), pages 215, etc.

4. See Williams' "Obstetrics" (1909), pages 225, 254, and 296; or Hirst's "Obstetrics" (1909), pages 312, etc.

5. See Williams' "Obstetrics" (1909), pages 809 and 815; or Hirst's "Obstetrics" (1909), pages 574 and 577.

6. See Williams' "Obstetrics" (1909), page 802; or Hirst's "Obstetrics" (1909), pages 563 and 564.

7. See Williams' "Obstetrics" (1909), page 369; or Hirst's "Obstetrics" (1909), page 567.

8. *Puerperal eclampsia* is an acute morbid condition, occurring during pregnancy, labor, or the puerperal state, and is characterized by tonic and clonic convulsions, which affect first the voluntary and then the involuntary muscles; there is total loss of consciousness, which tends either to coma or to sleep, and the condition may terminate in recovery or death.

And see Williams' "Obstetrics" (1909), page 541; or Hirst's "Obstetrics" (1909), page 635.

9. See Williams' "Obstetrics" (1909), pages 346 and 349; or Hirst's "Obstetrics" (1909), pages 928, etc., and 948.

10. See Williams' "Obstetrics" (1909), pages 643 and 649; or Hirst's "Obstetrics" (1909), pages 292, 295, 304, and 306.

GYNECOLOGY.

1. *Ectopic gestation* is gestation occurring elsewhere than in the cavity of the uterus.

See Williams' "Obstetrics" (1909), page 647; or Hirst's "Obstetrics" (1909), page 303.

2. See Williams' "Obstetrics" (1909), page 649; or Hirst's "Obstetrics" (1909), page 306.

3. *Three types of endometritis:* Simple, gonorrheal, and septic.

Tuberculous endometritis might be suspected in patients who had a tuberculous lesion elsewhere. The diagnosis might be confirmed by finding the tubercle bacilli in the endometrium.

4. *Uterine hemorrhage after the menopause* is of grave import; it may denote malignant tumor of the uterus (or cervix), or inflammation of the uterus or appendages.

5. *Three of the earliest symptoms of cancer of the cervix uteri:* Bleeding, offensive vaginal discharge, and pain.

Three conditions with which it might be confused: Cervical fibroid, adenoma of the cervix, and hypertrophy of the cervix.

6. *Three clinical symptoms of retroversion of the uterus:* Pain (dysmenorrhea), metrorrhagia, and leucorrhea. Treatment consists in replacing the uterus and then retaining it in position. The cause must be removed; pessaries, the sound, and tampons may be employed; adhesions must be broken up; lacerated perineum must be repaired; hysteropexy or shortening of the round ligaments may be considered.

7. *Five diagnostic symptoms of carcinoma of the breast:* Lymphatic involvement, edema of the arm, slow growth, cachexia, and ulcer with foul discharge.

8. All tears of the perineum should be repaired as soon as possible (unless there are contraindications). A primary operation is best because the edges are fresh and can be approximated; little (if any more) anesthetic is wanted; the woman has to lie in bed, and therefore only one absence from household work is requisite; infection is less likely. In any case, operation may prevent rectocele, cystocele, prolapse of uterus, and general weakness, malaise, and disability.

9. Dysmenorrhea. *Symptoms:* Pain during or in the neighborhood of the menstrual period, varying from malaise to agony; it is chiefly noticed just before or at the beginning of the period. There may also be evidences of tumor, inflammation, obstruction, malposition, or malformation of the uterus. *Four types:* Obstructive, ovarian, membranous, and congestive.

10. See Rose and Carless' "Surgery" (1908), page 1288.

In *pyosalpinx* there is generally some fever; the mass is elastic, and may fluctuate and is sensitive to pressure; there are often adhesions, and there is a history of infection. In *tubal pregnancy* the mass is apt to be firm and not sensitive to pressure; there are not adhesions; and there is a history of pregnancy with corresponding symptoms and signs. In the *appendiceal abscess* the infection is more often due to colon or tubercle bacillus than to gonococcus; tenderness is in region of McBurney's point; the mass is not generally felt by vaginal touch.

SURGERY.

1. See Rose and Carless' "Surgery" (1908), pages 546 and 547; or Da Costa's "Surgery" (1908), pages 525 and 531.

2. See Rose and Carless' "Surgery" (1908), pages 539, 540, 629, and 630; or Da Costa's "Surgery" (1908), pages 515, 517, and 601.

3. See Rose and Carless' "Surgery" (1908), pages 1005 and 1006; or Da Costa's "Surgery" (1908), pages 928 and 931.

4. See Rose and Carless' "Surgery" (1908), pages 1061 and 1063; or Da Costa's "Surgery" (1908), pages 965 and 967.

5.

CONCUSSION OF THE BRAIN.	COMPRESSION OF THE BRAIN.
Unconsciousness is incomplete; patient can be made to answer, though it may be briefly, and in simple words.	Complete unconsciousness; may scream into patient's ear at the top of the voice, but will receive no answer.
Special senses, though greatly blunted, are not abolished.	Special senses entirely suspended.
Power of movement not destroyed; if the position of a limb be changed the patient will resist or bring it immediately into the original position.	Complete or partial paralysis; in most cases hemiplegia.
Respiration is quiet and feeble.	Respiration full and noisy.
Pulse feeble, frequent, and intermittent.	Pulse full and slow, and sometimes laboring.
The stomach sickens and rejects its contents.	The stomach is insensible to any impression; no nausea or vomiting.
The feces may be discharged incontinently, as may also the urine, though not usually.	Bowels are torpid, and the bladder incapable of emptying itself, though the urine may escape by overflow.
Deglutition little impaired.	Deglutition difficult or impossible.
Pupils variable, though generally contracted; the eyelids somewhat open.	Pupils variable, though generally much dilated, and the eyelids closed.
Temperature of the body less than natural.	Temperature almost natural, a little below the normal standard.

—(From Treves' *Manual of Surgery.*)

Indications for trephining: Intracranial hemorrhage, abscess of brain, fracture of skull, epilepsy, tumors of brain, drainage of frontal sinus or mastoid cells, thrombosis of venous sinuses.

See Rose and Carless' "Surgery" (1908), page 758; or Da Costa's "Surgery" (1908), page 734.

6. Intracranial hemorrhage is the indication for ligature of the middle meningeal artery. See Rose and Carless' "Surgery" (1908), page 773; or Da Costa's "Surgery" (1908), page 704.

7. See Rose and Carless' "Surgery" (1908), pages 1046 to 1050; or Da Costa's "Surgery" (1908), pages 861 to 865.

8. See Rose and Carless' "Surgery" (1908), pages 1160 and 1161; or Da Costa's "Surgery" (1908), pages 1103 and 120.

9. With no further information than is given in the question, I would advise amputation, because so long as there is suppuration the bones cannot unite, and the gangrene is often an indication for amputation. This amputation should be performed well above the knee, where the arteries are sound. See Rose and Carless' "Surgery" (1908), pages 1315 and 1301; or Da Costa's "Surgery" (1908), page 1221.

10. See Rose and Carless' "Surgery" (1908), pages 926 and 929; or Da Costa's "Surgery" (1908), pages 773 and 774.

HYGIENE.

1. An *infectious* disease is one that is caused by a known microorganism; as typhoid fever, tuberculosis.

A *contagious* disease was formerly understood as one that was communicated by direct personal contact, as by touch, or exhalations from breath or skin; as measles, smallpox.

2. *Infectious diseases which may be conveyed through the medium of the air:* Tuberculosis, pneumonia, diphtheria, measles, scarlet fever, whooping cough, erysipelas, influenza.

Through the medium of food: Tuberculosis, diphtheria, typhoid fever, scarlet fever, cholera, beri-beri.

Through the medium of insects: Malaria, yellow fever, filariasis, typhoid fever, bubonic plague, tick fever, sleeping sickness.

To combat the insects, see these diseases in index of French's or Osler's "Practice of Medicine."

3. See French's "Practice of Medicine" (1910), page 505; or Osler's "Practice of Medicine" (1909), page 44.

4. *Five quarantinable diseases:* Cholera, yellow fever, smallpox, plague, typhus. For *length of time*, see these diseases in index of French's or Osler's "Practice."

5. "To trace an epidemic to its source is not so much a study for the doctor as for the statistician, the detective, the bacteriologist, the chemist, and the engineer." Find out who have the disease, where they live, and when and where they were taken sick; investigate the use and source of water, milk, and food among the sick. If food or milk can be traced to one dealer, or food to the same source, much is accomplished; inspection of farms and dairies may be necessary. Oysters and "carriers" must be remembered.—(From Whipple's *Typhoid Fever.*) And see French's "Practice of Medicine" (1910), page 107; or Osler's "Practice of Medicine" (1909), page 96.

6. See French's "Practice of Medicine" (1910), page 194; or Osler's "Practice of Medicine" (1909), page 207.

7. "An examination of the quality and purity of water for drinking purposes is a very complicated procedure requiring not only expert sanitary knowledge, but also a thorough training in chemical and bacterial analysis, and

a capacity for weighing and comparing all data gained in order to base judgment on them." (Price's *Hygiene and Public Health.*) Such being the case, I should send samples of the water and of the milk to the proper authorities, and should advise that pending their decision such water and milk should not be used, or that the water should be boiled and filtered before using.

8. *Three reliable fumigation agents:* Sulphur dioxide, chlorine, and formaldehyde.

To *fumigate by sulphur dioxide:* For each 1,000 cubic feet of space, three pounds of sulphur are burned, care being taken to prevent accidents. In all cases all apertures and crevices of the room should be closed, all closets, drawers, or other receptacles opened; and after the fumigation the room should be well ventilated and thoroughly cleansed with a solution of corrosive sublimate.

9. Hygienic precautions to be taken in treating a case of tuberculosis: "The patient's quarters should be free from dust and admit of spending many hours daily in the open air in all weathers, properly sheltered, and, if very ill, lying wrapped in a hammock or reclining chair. His bedroom should be well aired at night, draughts being avoided. The room should be uncarpeted and free from hangings. It should be often cleaned and periodically disinfected. All sputum should be collected in paper spit-cups, which should be burned daily. Smoking should be forbidden. Harm is done by any exercise which results in fatigue, and while fever exists it should not be attempted at all. Patients should be taught the necessity of practising lung gymnastics and breathing only through the nose, which should be kept clear and free from occlusion by secretions, or an hypertrophied catarrhal mucosa. * * * The clothing should be woolen, but not too heavy, or sweating is increased; and a flannel night-gown and loosely knit leggings should be worn at night in cool weather. The skin should be cleansed by daily sponge-baths of lukewarm alcohol and water."—(Thompson's *Practical Medicine.*)

10. *To secure and maintain a pure supply of cistern water:* The cistern should be properly built of the best materials; if any water is collected from roofs the first of such water should be allowed to run to waste so as to avoid contamination by anything that may have collected on the roof; the cistern should admit of easy inspection and cleansing, and it should be inspected and cleansed; the cistern should be covered, so as to exclude dirt, dust, animals, insects, etc.; light should also be excluded; the overflow pipe should discharge into the open air and should have its exit covered with wire netting to prevent the entrance of animals or foreign matter.

MEDICAL JURISPRUDENCE.

1. *Insanity* is "that state of disordered mind in which a person loses the power of regulating his actions or conduct according to the ordinary rules of society." (Taylor.).

"*The best classification for legal purposes*": (1) Idiocy; (2) imbecility; (3) mania; (4) melancholia; (5) monomania; (6) general paralysis of the insane; (7) dementia; (8) certain forms of mania without distinct etiological relations. (Dwight's *Medical Jurisprudence.*)

2. "*By superfetation* is meant that a second conception may occur during pregnancy, both children being carried through the double pregnancy, each being born at the full term; the interval of births is necessarily the same as that between the two conceptions.

"*Distinction from twin pregnancies:* These cases show an interval of only a number of hours or perhaps days between the births of the two children. The possibility of such an occurrence must be accepted, although they are extremely rare. Such cases, as far as is known, have never been brought into court. If they should be, one must recognize the possibility, and the questions must be decided by the development of the child and the recognized periods of duration of gestation." (Dwight's *Medical Jurisprudence.*)

3. *Impotence* is defined as the permanent incapacity for sexual intercourse; and *sterility* as inability to procreate, or a want of appetite in the female for impregnation.

4. *Elements of responsibility in criminal malpractice, and of relief from responsibility:* "A practitioner of medicine or surgery will be guilty of criminal malpractice: (1) When serious results follow on account of his gross ignorance or neglect. (2) When he uses medical or surgical methods which are prohibited by law. (3) When he makes use of unusual methods which are apt to endanger the life or health of his patient. (4) When he neglects to use such means as may be necessary for the safety of his patient. (5) He is liable for any bad result which may depend upon a want of knowledge or lack of care on his part. (6) He is required to exercise the amount of skill which may be reasonably expected from one under his conditions. (7) Gratuitous treatment does not relieve him from responsibility for the result. (8) He cannot be compelled to assume the care of any case without he so wishes, but, having accepted it, he cannot withdraw without giving suitable notice of his intention. (9) An action for malpractice cannot be brought after he has recovered in court for his services. (10) He is relieved from responsibility when the patient fails to follow his advice. (11) He is responsible for negligence or ignorance on the part of his assistants, but not for criminal acts on their part. (12) He is not responsible for errors in judgment in uncertain or difficult cases." (Dwight's *Medical Jurisprudence.*)

5. In the study of blood-stains the following questions have to be settled: (1) Are the stains caused by blood? (2) Was the blood of human origin? (3) If not of human origin, from what source did it come? (4) If of human origin, was it arterial or venous? (5) If of human origin, what can be learned as to the age, sex, etc., of the individual furnishing it? (6) Did it come from the living or dead?

The stains should be studied chemically by spectroscope, and by microscope.

To distinguish the human blood globule from that of other sources, a careful study is required of the shape and size, and presence or absence of nuclei. In case the question is between human blood and that from an animal whose blood closely simulates human blood, it may be very difficult or even impossible to determine between them.

6. In order to convict for infanticide, the law requires that it should be proved: (1) That sufficient uterine age and development have been reached to allow of a separate existence on the part of the child. (2) That the child was born alive. (3) Proof of the manner of death. (Dwight.)

7. *Post-mortem signs in the newborn after asphyxia:* These are not conclusive; but the lungs show lack of distention and aeration, and the circulation is in the fetal condition, the brain may be congested, and there may or may not be marks of external violence.

After strangulation: Marks of external violence are present, ecchymoses may be found, brain is congested, heart (especially the right side) is engorged with blood, ecchymoses are present on pleura and pericardium.

"The *post-mortem signs presented by exposure to cold* in the newborn are very meager; the congestion of the brain, a more or less rosy tint of the blood, is perhaps the most important. A very moderate degree of exposure is sufficient to cause death in the newborn, and in such instances signs presented in death are comparatively few. The *indications of starvation* are, at autopsy, even more difficult to present as a definite conclusion. *Elements of evidence:* A suspicion will be aroused when the body of a child is studied in which the respiration and circulation have been thoroughly established, the meconium absent from the intestine, and in which no milk or other food is found in any portion of the digestive apparatus. When death occurs from starvation it is usually combined with exposure in one form or another." (Dwight's *Medical Jurisprudence.*)

8. Death may follow lightning so instantaneously as not to modify the position which the body held at the time of the shock; or it may follow later as the result of burns and lacerations; it may be due to the shock to the brain and nervous system.

Post-mortem appearances: "In those cases of sudden death by lightning in which the body is left in the position occupied at the time of the shock post-mortem rigidity comes on at once. In other cases it may be slower in its onset, but usually is rapid as compared with death from ordinary causes. The conditions found after death from electricity are not consistent; neither are they such as in unknown cases would establish the cause of death. Many observers have reported the rapid following of decomposition, but there seems in fact to be little evidence that such is the fact. The heart may be filled with blood, which may be liquid or clotted. The blood is usually dark, but a case has been reported in which it was of a "rosy, vermillion" color. There is usually a passive congestion of the various organs, including the brain, and small hemorrhages into its substance have been found. Small superficial hemorrhages are usually found scattered over the surface of the lungs and heart." (Dwight's *Medical Jurisprudence.*)

The *medicolegal* interest is due to the fact that the victim of electricity presents certain conditions which simulate very closely the effects of homicidal violence.

9. See some good textbook on Pathology.

10. *Rape* has been defined as being the carnal knowledge of a woman against her will. But the element of will may or may not enter into the case; consent if it be obtained by fraud or from one mentally deficient, or under age, does not relieve the criminal from the charge of rape. Rape may also be perpetrated when the victim is unconscious or in such other condition as to interfere with the action of the will.

"Medical testimony in these cases has usually to do with three conditions: (1) The presence or absence of bruises, lacerations, or other signs of injury upon or about the genital organs. With regard to the evidence of lacerations of the hymen, it must be remembered that a certain number of hymens are so elastic as to permit of intercourse without laceration. (2) The presence or absence of spermatic or blood-stains upon the person or clothing of those concerned, and the presence or absence of spermatozoa in the vagina. (3) The presence of venereal disease in one or both." (Dwight's *Medical Jurisprudence.*)

BULLETIN OF APPROACHING EXAMINATIONS.

STATE	NAME AND ADDRESS OF SECRETARY	PLACE AND DATE OF NEXT EXAMINATION†	
Alabama*	W. H. Sanders, Montgomery	Montgomery	Jan. 9
Arizona*	Ancil Martin, Phoenix	Phoenix	Jan. 2
Arkansas	F. T. Murphy, Brinkley	Little Rock	May 14
California*	Chas. L. Tisdale, 929 Butler Building, San Francisco	San Francisco	April 2

*No reciprocity recognized by these States.

†Applicants should in every case write to the secretary for all the details regarding the examination in any particular State.

Alcoholism and Pregnancy.—Gentili and M. Cambazzu made an experimental study of the effects of alcohol on pregnancy. They injected animals with alcohol intravenously and subcutaneously, and found that this drug caused prostration in the mothers and feebleness and lack of resistance in the offspring, which soon died. There were functional and organic changes in the chief internal organs of the poisoned animals. Pregnancy generally went on to full term, but sterility was caused by the continued injections in cases not yet fecundated. Pregnant animals were more seriously affected than the non-pregnant. Abortion was not caused by alcohol, but in some cases the fetus was killed. Probably in the human race a degree of immunity to alcohol has been conferred by generations of alcoholic indulgence.—*Annali di Ostetricia e Ginecologia.*

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ended December 9, 1911:

	Cases	Deaths
Tuberculosis Pulmonalis	384	171
Diphtheria	304	15
Measles	317	6
Scarlet Fever	192	8
Smallpox	5	—
Varicella	233	—
Typhoid Fever	103	8
Whooping Cough	36	7
Cerebrospinal Meningitis	3	1
Malarial Fever	—	—
Totals	1,577	216

Experiments on the Pharmacological Effects of Salvarsan.—Ferrannini states that we know much about the therapeutic effects of salvarsan but little about its pharmacology. He has therefore instituted a series of experiments to ascertain its effects on the skin, mucous membranes, subcutaneous and submucous tissues, and endothelium of the vessels. His conclusions are that in the solutions generally used therapeutically it has no effect on the skin, mucosa, and endothelium of the vessels. It manifestly irritates the subcutaneous tissues, which explains the inflammatory process which is intense but generally ends in resolution. In subcutaneous injections the substance remains a long time in contact with the subcutaneous tissues, while when rubbed on the skin, instilled into the eye, or injected into a vein it remains for but a short time in contact with the tissues.—*La Riforma Medica.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended December 8, 1911:

Places	Date	Cases	Deaths
CHOLERA			
India: Calcutta	Oct. 8–14	..	15
Madras	Oct. 22–28	90	64

A SUGGESTED READJUSTMENT OF OUR VIEWS ON HEART EXAMINATIONS FOR LIFE INSURANCE.

BY CHAS. F. MARTIN, M.D.,

MONTREAL, CAN.

MEDICAL DIRECTOR OF THE STANDARD LIFE INSURANCE COMPANY, OF MONTREAL, CANADA.

A VERY limited experience in the medical aspects of life insurance, and the difficulty in obtaining from the literature an adequate conception of the subject are perhaps the best apology for venturing to appear before this distinguished body to offer any suggestions as to methods of insurance examination. It is especially with reference to a consideration of a more lenient appreciation of life values than that entertained to-day by many insurance companies that the present paper deals. If perchance in these remarks anything may be found which will promote a healthy discussion as to the means of gathering statistics in cardiovascular conditions for insurance purposes, and remodeling our present over-conscientious proscription, the time may not be altogether wasted.

That the views of all insurance companies regarding medical examinations have undergone some radical changes in recent years need not be mentioned here; that much, however, of old-fashioned dogma still exists and prohibits the acceptance of all sorts of reasonable risks will, I think, be obvious to most of the members of this organization. Up to a few years ago, for example, the presence of a few casts or a trace of albumin in the urine of an applicant was sufficient reason for declination even when over fifty years of age; to-day the incidence of these symptoms is not usually regarded in so serious a light, although many companies still decline to be lenient with such cases, even in the absence of any of the collateral signs of serious disease. As everybody knows, these signs may exist for thirty to forty years and more, without resulting fatally, and if only a proper appreciation of the underlying conditions existed the insurance companies would receive the greater benefit by their acceptance. Even to a greater degree does this hold for examinations of the cardiovascular system, and the revolutionary alteration of our views within the last decade or two has been, I think, rather disregarded by the medical referees of at least some insurance companies. As Dr. Porter has recently stated in his most interesting and valuable suggestions to life insurance examiners, more errors occur in connection with diseases of the heart than in any other part of an insurance examiner's work.

In examinations of the heart, for example, I know well it is the practice of many examiners to be satisfied with the auscultatory phenomena alone, and in the absence of any adventitious sounds to declare that portion of the applicant's anatomy as healthy. (I leave out of discussion those physicians who neither strip their applicant's chest, nor even bother about the more careful method of inquiry and analysis, as being worthy of professional ostracism, and yet I am familiar with those who scout the idea of troubling their applicants or themselves with any such labor.)

Now while in the past most stress has been laid on the use of the stethoscope and the palpation of the pulse, I think one may safely say that the modern view inclines much more to the idea that the detection of a murmur is probably only a minor feature upon which to base a prognosis. For years it has been my custom to teach students that the use of the stethoscope is the last and perhaps the least important portion of a cardiovascular examination, being at all events quite subordinate to the history, the subjective symptoms, and complaints, for these are, after all, the chief evidences of the true efficiency of the heart and vessels. Following upon a careful analysis of the symptoms for evidence of cardiovascular disturbances, comes the consideration of the causes of these symptoms, whether (*e. g.* dyspnea) due to disease of the heart itself or to some functional disturbance elsewhere. These observations aid in estimating the condition of the heart wall, which for practical importance gives the best clue as to the possibilities of the heart's power, and then, but only then, should we consider whether a valve is affected, and, if so, which special one is involved, for the mere detection of a valvular defect affords but little criterion as to the prognosis.

Let me make it clear that I have no wish to minimize the value of auscultation; far from it, but merely to insist that from the prognostic point of view this method takes a very subordinate position. Take for example the individual with marked signs, on auscultation, of mitral stenosis, with no rheumatic attacks or chorea for years, and whose compensation is well maintained, and there can be no logical basis from the auscultatory phenomena alone to determine whether his years will be few or many, for it is all too well known that in the absence of ordinary signs of heart failure life may be prolonged in practically good health for thirty or forty years, and longer. This question of murmurs arises naturally out of what has just been said, and one cannot but feel that practically all insurance companies tend to overestimate the gravity of such existing conditions. Murmurs, *per se*, have a widely varied significance. Even the organic murmurs are merely evidences of disturbed function, through varying degrees of anatomical changes in the valves, often, indeed, without any valve disease, and in themselves do not necessarily imply a shortening of life, though of course presenting a certain de-

gree of impairment which is only manifested under special conditions, as excessive strain, or severe acute disease or injury. To regard the mere existence of, say, a mitral murmur, even with a previous rheumatic history, as *per se* a grave omen, or a cause of rejection for life insurance, seems to blind oneself to the more accurate knowledge acquired from recent investigations. Dr. Heron, who some years ago was a leading authority on life insurance in England, considered any applicant with mitral regurgitation as positively unworthy of acceptance, chiefly for the reason that it is impossible to control the mode of life and habits of our applicants, and that at any time a sudden supreme effort, such as running to catch a train, would precipitate heart failure. It was for this reason that the same physician was so severe with all suburban applicants. Such a generalization would seem to leave out of consideration several important factors, each of which is of the utmost use in determining the value of the heart's efficiency. For, to obtain accurate knowledge of this point, we must above all things learn to appreciate the predominating influence of the heart muscle, the use of the valves, the significance of mitral regurgitation, and other valve defects in relation to the patient's general condition and any associated lesions.

In passing I would like further to insist on the relative unimportance of the site of the apex beat, *i. e.* of the cardiac impulse, which is remarkably variable within normal lines depending on posture, on amplitude, and on force. In this way variations of one inch may be found in normal individuals, and the impulse may alter with abdominal distention, with a high dilated stomach, and with respiration. A convincing demonstration of this last variation is easily found by radioscopy, and the marked alterations downward and to the right with full inspiration readily visible. The size of the heart, too, is normally a most variable quantity; there is, indeed, no fixed size of the organ. The important function of tonicity of cardiac muscle allows amply for such a variation, and takes care of altering magnitude as it ordinarily occurs with the respiratory movements, and under conditions of effort—in fact, wherever temporary dilatation of the heart occurs in response to temporary increased need of space within the chambers. This, too, is a normal process, a mere physical dilatation, also demonstrable by means of the fluoroscopic screen. The importance of the heart muscle will be referred to in connection with the consideration of abnormal rhythm, and the question of valvular lesions will be discussed first. Now by mitral regurgitation, I presume, is meant a leakage through these valves, or, to be more explicit, a murmur heard at or near the apex and transmitted more or less toward the axilla. Even the inexperienced physician knows that such murmurs may occur in healthy individuals after exertion, a fact which has led to the rather suggestive idea that the valves, instead of being meant solely to prevent leakage, are something more, and in a certain sense safety valves. No less an authority than James MacKenzie has expressed this view, and that one of the important functions of the heart valves is to leak under strain; so that mere leakage is not to be regarded as an unfailing evidence of cardiac disease.

It is customary to speak of murmurs not due to organic disease as accidental or functional murmurs, and one of the common sources of error in life insurance examinations arises, I think, from a faulty appreciation of the frequency of these accidental sounds at any orifice and with any period of the cardiac cycle. In a general way accidental murmurs are supposed in the majority of cases to be basal and systolic, while any systolic murmur heard at the apex and transmitted to the axilla is regarded by many as an almost certain sign of valvular disease, or, at all events, of organic cardiac defect. Any such conception is, as you all know, an absurdity, for all too frequently do we find harmless and transitory murmurs which are not basal, or hemic, or cardiorespiratory in origin, but, on the contrary, simulate in site and rhythm the organic murmurs, and still in no sense whatsoever do they impair the efficiency of the cardiovascular system.

I should like to insist upon this point, on the fact that many accidental murmurs occur with systole at the mitral area, or all over the precordium at any orifice—that some, too, are diastolic and yet transitory; that with anemia they may be heard at the pulmonary, or mitral, or tricuspid areas, and very often give rise to temporary tricuspid regurgitation, without ever inducing heart failure. Furthermore, many murmurs occur as a result of acute infections at any orifice, and are the result of a temporary involvement of the muscular ring or papillary muscles, and as such are often easily and rapidly repaired without affecting in any way the permanent normal efficiency of the organ. Clinical and pathological studies in typhoid and other infections have proved this without a doubt—nor is this a recently acquired fact. Sir Andrew Clarke drew attention to this in his interesting studies of chronic valvular conditions. Not only were a large proportion of these 684 patients quite unaware of the existence of any cardiac disturbance, but consulted him for complaints referable to other organs and tissues. He dilates on the coexistence of murmurs with longevity, and he, too, lays stress on what has just been mentioned concerning the temporary character of many of these murmurs, that organic valvular lesions very often heal so completely as to cause the disappearance of murmurs which may have followed some infection, *e. g.* rheumatism, chorea, etc., for several years. Indeed, Clarke goes so far as to say that the great majority of murmurs occurring with chorea eventually disappear and adds that he can remember but a few instances in which the mitral bruit of chorea has continued to be clearly heard ten years after its appearance. Organic structures, then, can be so completely repaired as to leave behind no clinical evidence of their former existence.

Tricuspid regurgitation, up till recently looked upon as a final stage of heart disease, is now recognized as a common and often transitory condition in all sorts of general debility from one cause or another. Indeed, John Hunter many years ago doubted the competency of this valve in normal hearts, owing to the small size of its cusps, while Gairdner and Gibson produced the condition artificially with ease, while others have proved its fugitive and harmless nature. In fact, tricuspid regurgitation is sometimes physiological and associated with the normal function of tonicity.

It would seem, then, quite wrong to subdivide our cases of cardiac disease where murmurs exist into two great stages: First, that with good compensation, and second, that in which compensation is broken, under the impression that the second state inevitably succeeds the first. As MacKenzie has shown, this is undoubtedly wrong, for in the

majority of patients, even with organic murmurs, heart failure is not necessarily a sequence, even in late life. Sir Andrew Clarke's statistics show this clearly, and James MacKenzie in recent publications has dwelt on the comparative infrequency of heart failure in cases of valvular disease. Thayer in a recent study of the heart murmurs, examined thirty robust schoolboys to find eighteen with murmurs, thirteen of which could be heard all over the precordium, in the recumbent or left lateral posture. Apropos of the frequency of functional cardiac murmurs he is led to remark on "the number of men who are refused by insurance organizations, whose career is cut short in the army and navy, because of lack of appreciation by overconscientious examiners of just these points, and this is really large." Out of fourteen young men examined by him because of some supposed cardiac defect, and consequent rejection or postponement on the part of a well-known company, practically all were perfectly eligible.

The records of the Royal Victoria Hospital, Montreal, illustrate well the frequency of murmurs. Out of 5,000 medical cases admitted to the Royal Victoria Hospital Dr. J. C. Meakins and R. M. Hardisty found that

1,826 cases had murmurs or irregularity, 36 per cent.
1,736 cases had murmurs (irrespective of irregularity).
336 cases had irregularity (irrespective of murmurs).
1,490 cases had murmurs (without irregularity).
92 cases had irregularity (without murmurs).
244 cases had murmurs and irregularity.

Organic diseases with murmurs:

762 cases had organic murmurs.
210 cases had organic murmurs (with irregularity).
552 cases had organic murmurs (without irregularity).

Functional conditions with murmurs:

972 cases had functional murmurs (at one or more orifices).
34 cases had functional murmurs (with irregularity).
938 cases had functional murmurs (without irregularity).

Organic diseases with irregularity:

248 cases had organic irregularity.
210 cases had organic irregularity with murmurs.
38 cases had organic irregularity without murmurs.

Functional conditions with irregularity:

88 cases had functional irregularity.
34 cases had functional irregularity with murmurs.
54 cases had functional irregularity without murmurs.

It is interesting to note the state of compensation in these cases:

Good, 342; fair, 213; failing, 99; broken, 146. As regards etiological factors in the organic cases it is likewise important to note that out of the 800 cases of organic disease (out of 5,000) there were 224 in which no cause could be assigned. An analysis of sixty autopsies was likewise made with a view of establishing the relations between clinical signs and anatomical appearances, and, while time did not permit a further investigation up to the present, one interesting fact is revealed, viz., that in five cases where there were clinically no signs of disease the heart is described at autopsy as fatty.

Some plan, then, would be of use by which examiners might report with more satisfaction a reasonable estimate of the prognosis, for where doubt exists as to the significance and origin of a murmur and its effects on longevity the mere report on the auscultatory phenomena is far from sufficient. To illustrate by one example, the considerations which in a general way should guide the examiner, particularly with reference to mitral murmurs, are as follows: The murmur having been detected, the extent of the valve lesion should be estimated, if possible, in part by the size of the heart and character of the murmur, and still more by the symptoms of regurgitation. Such symptoms, manifested as they may be by signs of an embarrassed heart (*e. g.* dyspnea), afford the most satisfactory clue to the limitations of effort, and careful inquiries will alone make such a decision possible. In the same manner we ascertain to what extent the muscle is damaged and thereby the efficiency of the heart. If there be no failure of cardiac response and the size of the heart be normal, such cases should be acceptable (with perhaps certain small limitations) for insurance. If, on the other hand, there be signs of muscular impairment, we need not exclude such a risk without first ascertaining the degree of progress of the malady, for if there be no progressive increase of inefficiency after some years, the risk is still a possible one. The source and origin, too, are important considerations, for if it be of infectious nature the date of its onset would be important. Thus a lesion that is progressive within two or three years is much more grave than in those cases dating back ten or fifteen years, even though the heart be enlarged and some failure of cardiac response be evident. A modified prognosis is certainly due to such cases and a short term policy reasonable. This is especially the case with endocarditis of rheumatic or choreic origin, though not with cardiac lesions of the degenerative variety, *i. e.* associated with sclerotic changes, where the prognosis is always more grave.

The age, too, should modify the consideration of the risk, for in youth the prognosis is entirely different from that in later years. So, too, in the same way the duration of lesions has its important bearing on prognosis, and those which date back for years without obvious changes are to be regarded as much more favorable. One need not add that the occupation and habits have likewise an important bearing on the prognostic values. It is thus obvious that where murmurs exist many factors require consideration before a final rejection, and that many instances occur in which a policy may be accepted without detriment to the company.

Arrhythmias.—Far more significant of the revolution in the interpretation of cardiovascular phenomena is the change which medical investigation has produced in our views on the cardiac irregularities. And yet, with all the literature issued on this important subject, I venture to say that but few of our field examiners are cognizant of more than the most superficial facts. Indeed, until a few years ago, even our textbooks contained but little that was satisfying, and the knowledge concerning the clinical significance of these phenomena is as yet not very widespread. Ask our examiners, for example, the varieties of extrasystoles, the meaning of the refractory period and the compen-

satory pause, and how few will supply an intelligent answer. Even the fact that the form of irregularity is of far more importance than is its intensity is probably not usually recognized even yet.

The types and causes of the arrhythmias are multiple. Indeed some are purely physiological. More than one authority has drawn attention to the frequency of respiratory arrhythmia, for example, so common in youths from seven to fifteen years of age, as well as in neurasthenics of any age. As everyone knows, the heart-beats vary in rate with respiration, being more rapid with inspiration, and the pulse may under these conditions be so accelerated as to be almost imperceptible. This is not pathological, but associated merely with a varying irritability of the vagus center. Holding the breath usually stops the irregularity, as does also the injection of minute doses of atropine. The orthostatic type is another physiological arrhythmia, depending on posture, and in no sense pathological. No doubt in the majority of irregularities the heart muscle is of greater significance than is any other factor, and yet but few are inclined to respect its predominating influence, or even care to think of its two well differentiated muscular systems. How few of our examiners have learned to recognize the influence of the smaller system of cardiac fibers (the primitive bundle of His) upon the larger system, comprising the great bulk of heart muscle, and which is dominated and controlled in its activity by it. How hard to realize that the vast bulk of cardiac muscle may be normal throughout and yet a minute lesion of that other microscopical bundle may disturb the rhythm to a very marked degree. With the bulk of muscle unimpaired the power of the organ remains unaffected, even though its rhythm be altered, just in the same manner as in disseminated sclerosis the coordination of our voluntary muscles is disturbed without otherwise altering their efficiency. Vice versa, the larger muscular system may be diffusely disturbed by fibroid or fatty change, and heart failure may be imminent, and yet the rhythm will remain normal so long as the lesser system (of His) is preserved and its power of conduction and stimulation unaffected. The degree of arrhythmia, then, is no criterion of the heart's power, nor the intensity of the lesion, but the character of the irregularity determines the location of disease and, as such, gives a valuable clue to the prognostic significance.

The pathological types are not difficult to classify, and the extrasystoles here, too, form the largest class, including as they do many varieties hitherto kept apart, *e.g.* pulsus bigeminus and pulsus trigeminus, some varieties of paroxysmal tachycardia, abortive heart beats, etc. It is noteworthy that more than half of all cardiac arrhythmias are due to extrasystoles, and yet a very large proportion of these has no grave prognostic omen. According to the type of the arrhythmia, to the length of the compensatory pause or its complete absence after an extrasystole, the source of irregularity may be localized with a considerable degree of accuracy, for extrasystoles of the sinus or auricle are not usually followed by a characteristic compensatory pause, which is the reverse of what happens with the ventricular type of this form of arrhythmia. Certainly there is no difficulty attending the detection of an extrasystole, *i.e.* the premature beat felt at the radial pulse and followed by a long pause. Sometimes, it is true, the finger fails to detect the second pulsation because of its small volume, and then auscultation at the heart will reveal the true nature of the defect. A comparison in this way of pulse and heart beats is sufficient, for an intermittency of the heart is a rare and grave phenomenon. The subjective complaints often describe the condition with accuracy, for the sensation of fluttering or the compensatory shock are often obvious to the patient.

The extrasystoles with their manifold causes must be classified if we would use any system for life insurance work, for the prognosis varies entirely with the cause. For example, auricular extrasystoles, occurring as they often do only with a serious disease in the auricle, will sometimes show elsewhere enough evidence of cardiac injury to enable one to appreciate their gravity. But sometimes, too, they are found with harmless conditions and the distinction is not easily made. The ventricular or auriculoventricular extrasystoles vary in gravity according to a number of causes. In general one may say that three classes of patients with extrasystoles must be regarded as unsatisfactory risks: (1) those with previous cardiac disease, (2) those with advanced arteriosclerosis, (3) those with arterial hypertension; because in all three some myocardial degeneration is obvious. Where, on the other hand, no lesion is otherwise evident the prognosis depends on the age, being good in the young and healthy (according to Mackenzie a specially good sign of health), while in those over fifty it is often the first cry of distress from the bundle of His, and, therefore, a sign of myocardial disease. Even then, however, it does not necessarily imply the onset of cardiac failure. In other cases toxic causes exist, and the abstention from tea, coffee, or tobacco will produce cessation of the arrhythmia. In yet another class digestive disorders from excessive or too fast feeding, gaseous distention, etc., bring about the extrasystoles, while in others, a very large proportion, these arise from nervousness or else no known cause can be assigned, and in these valerian or belladonna may cure the phenomenon and demonstrate the obviously good risk for a life insurance proposition.

Paroxysmal tachycardia comes under the same heading, being made up according to some writers of a succession of extrasystoles, while according to others it is more obscure and accompanied by a ventricular form of the venous pulse. Here, too, one should distinguish carefully between two forms, the one homogenetic of the physiological type, the other heterogenetic or true paroxysmal tachycardia. In the true condition the onset and offset of the tachycardia come and go suddenly, while in the homogenetic variety the paroxysms of tachycardia are of a simple nature, due to exercise, excitement, or convalescence, the change of rate being gradual during several minutes, and the rhythm normally maintained. Not so in the true variety, where one or two cycles suffice to induce the altered rhythm. A guarded prognosis must always be given along the lines above suggested for varieties of extrasystole, but at best the condition is admittedly obscure. Certainly people with this manifestation are to be regarded more seriously than those with ordinary extrasystoles. Bradycardia often is but a mistaken extrasystole which is missed at the pulse, thus producing a false bradycardia where the heart beats occur but do not reach the wrist. In the true bradycardia of long duration a lesion of the bundle of His may be at least suspected and those of ex-

perience will hold severely to a guarded prognosis. Perpetual arrhythmias form yet another type, with likewise two varieties: in the one with serious and grave prognostic omen, in the course of asystole, in the other not necessarily of immediate danger, but requiring at all times a guarded prognosis, because even when occuring in the midst of good health it suggests that the heart is menaced by serious changes. This whole subject with its varieties of auricular fibrillation may be dismissed with the one caution that no wise examiner will ever grant acceptance to an applicant thus affected, so difficult is it to determine what the outcome will be.

Merely a word may be mentioned concerning another variety, and that a very serious one, the pulsus alternans (really heart alternans) occurring as it almost always does when there is imminent danger of asystole, and a grave prognosis must be given. Indeed, it is the only form of irregularity which *per se*, and apart from any other sign, is of grave prognostic significance. This arrhythmia is really a change in volume of the pulse, not one of rate, its feature being the alteration of a strong pulse and a weak one, the heart's contraction corresponding to the weaker.

The incidence of irregularities as occurring in the Royal Victoria Hospital among 5,000 patients, with all forms of disease admitted to the medical service, may give some clue as to the frequency and importance of this phenomenon (*vide supra*). It is thus evident that irregularities of the heart from the insurance examiner's standpoint have considerable significance, for the majority of individuals who apply for policies and who present this phenomenon expecting acceptance will be as eligible as any other healthy risk. The important feature is that field examiners should be taught some system by which these examinations should be made, and thus render the perusal of reports more satisfactory.

Blood pressure forms yet another subject of doubt and disturbance to the majority of examiners to-day, for who is there, after all, who is qualified to speak with authority of its prognostic features? Perhaps none of the newer methods for cardiovascular examination has been so much in vogue with the average practitioner of medicine as is the estimation of the blood pressure. The systolic pressure is taken and, if found normal in the absence of physical abnormalities of the heart, it is apt to be taken for granted that this augurs well for the patient; and vice versa with a high blood pressure, in spite of anything in the chest, the prognosis is considered grave and such an individual is liable to rejection by an insurance examiner. And while, of course, both of these ideas are quite fallacious after all, our knowledge as to the significance of blood pressure is extremely limited, and stands in need of further assistance. A high blood pressure is often a most salutary incident in a man's life, and is protective. The older we grow the less pervious do our finer arteries become, and the greater is the need of a high pressure to nourish the tissues. Hypertension then should not be regarded as a disease, but often as a distinct benefit. Often on finding such hypertension we do all in our power to lessen it, when, as a matter of fact, our efforts should be directed toward maintaining it. The causes of increased pressure, while recognizable in certain diseased states, such as chronic arteriosclerotic nephritis and allied conditions, is yet quite inexplicable in others. Interesting, indeed, are those comparatively rare conditions in which an extreme grade of hypertension occurs without any appreciable cause, neither arterial sclerosis in any form, nor any old nephritis, and yet these patients will die sometimes from cerebral hemorrhage, sometimes from some other local arterial change, and always in the absence of any general discernible cause.

There are those who do not believe that hypertension *per se* has any grave significance, and that only when associated with definite visceral lesions does it assume any prognostic importance. The great fallacy seems to be this, we take the systolic blood pressure and learn that it is high, say 180, and regard this observation as symptomatic of a shortened life and give a serious prognosis. Many individuals may live for years with a high tension pulse, and the mere registration of a single numerical sign does not signify equally for every individual. The relation between the state of the circulatory power and the demands of the whole life capacity is an individual affair, and cannot be treated as a broad generalization. Each man has his own pressure index, and one can only form a rational idea of his life value by an attention to all the collateral symptoms and signs. In this matter, indeed, the physician's good instinct and intuition are of quite as much importance as is the functional diagnosis.

Great varieties in the technique of blood pressure estimation, the ever-increasing types of new appliance, and the neverending discussions as to its significance demonstrate how far from complete is the present status of our knowledge of this subject. Inaccuracy of greater or less degree seems possible in a remarkable variety of ways. The temporary influence of psychic and of vasomotor conditions upon blood pressure is too well known to call for more than a passing comment. The slighter inaccuracies associated with the nature of the vessel, its position, and the character and amount of the surrounding tissues are all-important factors in passing judgment on this method. One estimation is in itself subject to error, and repetition of tests is alone reliable. The proper standardization of certain forms of appliance now in vogue is all too necessary to ensure correct results, while any instrument depending to such an extent as most of these do upon the personal equation are certain to give rise to results that are far from scientifically accurate. Where this is however eliminated by the use of an indicating dial the possibility of error becomes minimal. (Pachon, Hill and Barnard, Singer.) More recent observations, too, have shown that the mere taking of the systolic pressure alone gives no clue to prognosis, that one must add to this the diastolic pressure and judge from the difference between the two as to the cardiac power. Nor is this all; where the pressure is high and the difference between the maximum and minimum is small, the prognosis and treatment are very different from those cases where a low pressure is recorded even with an analogous difference between the two.

Martinet's recent work in this connection is suggestive, as is that of many others who have endeavored to show the importance of correlating the two pressures. For the maximum blood pressure is but the expression of the intraventricular force, while the minimum indicates the degree of peripheral resistance, including not only the condition

of the arterioles, but also the viscosity of the blood, the friction incurred, etc. And the difference between the two alone gives an idea of the cardiac power. Of chief importance remains the great fact that blood pressure is merely a subordinate phenomenon, while the subjective symptoms are of far greater importance for prognosis. "Has the individual dyspnea on exertion?" is, thereofre, a more important question than "What is his blood pressure?"

Suggestions and Conclusions: Each individual must be judged entirely on his own merits and not subjected to any generalizations regarding presence of murmurs, irregularity, blood pressure, or other signs indicative of cardiac disturbance. Good general health, with fair habits, and no general symptoms of trouble with the cardiovascular system are all most important indications even apart from the findings on physical examination. The significant test of the individual applicant is in estimating what the French well designate as the *valeur globale de l'organe, i. e.* the combination of history, general examination, visceral reactions, and functional symptoms. The age, the history, and the mode of life, as regards occupation, amusements, work, food, anxiety, insomnia, and various affections of the body, all these are even more important than the physical findings. In other words, one must test the field of cardiac response to effort and exposure, as regards dyspnea, palpitation, pain, exhaustion, sense of compression or suffocation, all these symptoms being mere indications of the cardiac power and not at all signs of heart failure in its developed form. Irregularities should be carefully studied as to their cause and site of origin, and not be considered as synonymous with rejection. Moderately high blood pressure should not be recognized as sufficient to reject *per se* without due consideration as to the state of cardiovascular equilibrium. A normal blood pressure may exist with extreme fatty heart, and mislead even more than would a hypertension, if one lays too much stress on the virtue of normal pressure, for many a patient with fatty heart shows no alteration of physical signs, though marked failure to respond to exertion. In many cases of angina pectoris the signs and symptoms are so few that a careful history alone will reveal the diagnosis. "In functional heart disease the signs are more important than the symptoms, in organic trouble the symptoms are more important than the signs." In all forms of disease with murmurs, irregularities, etc., there is always the chance of accidents, embolism, malignant endocarditis, sudden death, strain with acute dilatation; but there is danger, too, of the healthy resident of your fair city being run over by an automobile and killed.

In conclusion let me suggest that the greater appreciation of cardiovascular risks will best come when proper forms are issued to every examiner with special reference to these questions, and the chief medical officer will have on paper a rational, accurate, and intelligent interpretation of the risk upon which he is asked to pass judgment.

Water Content of Fat Tissue.—O. Rozeurad notes that the fat of well-nourished individuals contains one-half as much water as that of lean and cachectic individuals. The increased water-content of the various organs is also noted in the latter, which fact is probably to be explained on the basis of some protective rôle in metabolism.—*Deutsches Archiv für klinische Medizin.*

CHRISTIAN SCIENCE IN OPERATION.

By HENRY DWIGHT CHAPIN, M.D.,

NEW YORK.

A few months ago I wrote an article entitled "Christian Science and the Child" (*The Independent,* June 29, 1911) in which I showed that the fallacies and not infrequent cruelties inherent in the practise and belief of Christian Science were best exemplified in the case of children. My object in writing this article was to try and aid in producing a public sentiment that would keep helpless children out of the hands of Christian Science practitioners. A reply was written by Mrs. Augusta E. Stetson under the title of "Christian Science and the Medical Profession" (*The Independent,* August 17, 1911). This consisted of the usual extravagant claims combined with vague and high sounding sentiments, enforced by many capital letters, that pass for argument with this cult.

It hardly seemed necessary to treat this article seriously, but the recent death in this city of a five-year-old child suffering from diphtheria may serve to emphasize a few points I then tried to bring out as well as two features in the reply which are typical of the thought and action of these people.

Experience shows that a certain class in every community is impressed by the pronouncements of the various cults claiming psychic or supernormal powers. The trained mind, accustomed to weigh and analyze evidence, can easily detect the fallacies and partial truths that are covered by the vague generalities of many of these cults. The unthinking may not find it so easy. The medical profession, as the guardian of the public health, should take more pains to enlighten the people as to the dangers underlying many of these systems.

In one of its aspects Christian Science may seem to present a comparatively harmless side, in another it appears ludicrous and absurd, but in a final estimate it is always liable to show a cruel or tragic side and the helpless child is here liable to be the chief sufferer. These facts are perfectly understood by educated physicians, but it may be wise to emphasize one or two points for the benefit of the laity.

Each one of these systems usually claims that it alone is successful in treating disease and warding off trouble. In this familiar vein Mrs. Stetson states that any lack of success is due to a defective application of Christian Science principles. One can not help noticing that there are many different cults at present aiming to influence bodily function by the exercise of mind or will power. Everyone knows that all these sects have more or less influence in selected and special cases. The mental composure that some nervous and imaginative people derive from these faiths is given as a sort of explanation as well as palliation of their existence. A similar composure as well as a partial success in certain kinds of healing is attained by East Indian fakirs in the same manner as by any so-called Christian sect, both aiming to produce in the brain an abnormal state of either quiet or excitation.

The root principle of all these systems, no matter how diverse their apparent action may be, is always the same—suggestion. There is probably no principle so widely applied in every-day life, consciously and unconsciously in various ways. It undoubtedly has a place as an aid in the treatment of disease, especially of the nervous variety. Every successful physician sometimes employs suggestion in connection with other treatment in certain ail-

ments so far as he can hope for beneficial results from its use. This is very different from its exclusive employment by those who are ignorant of the structure and functions of the human body and of the natural history of disease. It is proper to add that permanent benefits from treatment by suggestion in real disease are comparatively limited and untold harm often results from the efforts to use it to the exclusion of rational treatment.

When we see a neurotic individual relieved of forebodings by the various methods of mental impression, whether called faith cure, new thought, mental healing, or Christian Science, the sympathetic friends shake their heads and say "there must be something in it." There is something in it—always the same "it"—one of the diverse forms of mental suggestion. A careful observer may likewise see that many of the extreme forms of suggestion end in an atmosphere of delusion in which the facts and realities of life have small place. Trouble and sorrow seem to fade away in a blunting of the senses by a sort of autosuggestion. A state of mind is now reached in which one dodges the actual problems, diseases, and tragedies of life by denying their existence.

What an easy way to rid oneself of the difficult labor of dealing with hard facts! One does not know which to consider greatest, the laziness or the effrontery of this method.

I have no means of knowing who consider themselves true Christian Scientists, but we all know that all kinds are equally dangerous in the treatment of such severe and communicable diseases as scarlet fever and diphtheria. Mrs. Stetson claims that she has treated "hundreds of cases of measles, typhoid, scarlet, and slow fevers," and she thinks with success. Assuming that part of these illnesses were properly diagnosed, the final results must be unknown.

How can people who confessedly have not made a scientific study of the pathology and natural history of disease give reliable reports as to the results of any treatment or no treatment? Many of them deny the real existence of the very diseases they pretend to cope with successfully. Every thinking layman must realize that reports and statistics of ordinary or miraculous cures from such a source cannot stand any real investigation for a moment. Yet such statements sometimes influence people who are not accustomed to verify claims when positively made. When these assertions are coupled with generalities that sound elevated and pious, such as "spiritual thought will neutralize and cast out the qualities of the carnal mind," the unthinking may be impressed.

With these lofty utterances Mrs. Stetson and other healers have treated cases of scarlet fever. Those who have scientifically studied this malady are constantly looking for some of its insidious, severe, and permanent complications. Some cases, however, as we all know, are very mild in type and need no special medical treatment except careful watching for complications and an avoidance of the spread of infection to others. The only way to detect these complications is by careful examination of the vital organs liable to be affected by the poison of the disease. Christian Science healers are not competent or able to do this, so that the eventual result in their cases are unknown

One of Mrs. Stetson's cases having a "claim of diphtheria" . . . "passed on." How many other cases of infectious diseases thus treated finally "passed on" or are now passing through life with crippling and avoidable complications from lack of proper management, neither she nor anyone else will ever know. Neither will it ever come to light how many cases of scarlet fever and similar dangerous infections have been spread to others by this sort of treatment. Here lies the most serious social aspect of this question.

A teacher in an uptown public school recently told me of the sad death from scarlet fever of one of her most promising pupils. Investigation showed no possibility of infection in the home and apparently no cases in the class at school. The mystery was soon after solved by a Christian Science mother telling the teacher that her child, in the same class, recently had a "false claim" of scarlet fever which she had controlled in a few days so that the child was sent back to school. Comment is unnecessary. Careful, conscientious teachers are very much afraid of this cult after seeing such things happen.

I know of a recent case in which another Christian Science mother sent for a physician owing to the peculiar appearance of her boy's skin. It proved to be a mild but distinct form of measles. The rash naturally began to fade in a few days, when the mother telephoned the doctor that the child had not had measles and she was sending him back to school. The whole class was thus exposed, as the case was still infective, since the mother did not believe in measles. Many irregular systems of medicine get great credit from their handling of the milder types of the exanthemata. We all know, however, that the milder forms are the most dangerous in respect to the spread of infection and that a light case may produce a malignant and fatal attack in another.

Two cases of tuberculous peritonitis have come to my attention in connection with Christian Science. One I personally saw in consultation in a neighboring town. The only chance for life lay in an operation. It happened that in this vicinity the Christian Science cult was active and some of the mother's friends were of this belief. They assured her that if the case were put in their hands a cure would result and that the uncontrolled fears of the mother herself were largely responsible for the suffering of the child. Saner advice being finally accepted, an operation was performed, the tubercles located, and the child made a slow but perfect recovery. The boy would surely have died without this scientific interference as the disease was alike demonstrated and relieved by the operation. Here a precious life was nearly sacrificed to this delusion.

Another case of turberculous peritonitis did not turn out so happily. A mother with an only child was visiting friends in a distant city. These people were ardent Christian Scientists and when the little boy began to fail with obscure symptoms they sent for one of their cult to take charge of the case. The healer proved to be a young woman with a placid personality and sympathetic smile who assured the anxious mother that the "error" would soon be corrected. After weeks of suffering in which the child steadily grew worse, a physician was called in who found the case to be in the last stages of tuberculous peritonitis and too late for operation. The child died in a few hours after the smiling healer had taken her departure.

What about the religious side? Many members of the medical profession, although they are not always talking about it, both know and try to apply

the teachings and spirit of true religion, and nearly all recognize the spiritual side of human nature. This does not lead them to try and detach the spiritual from the material as both are exemplified in actual life.

It must be remembered that to some, Christian Science, apart from its sordid and commercial side, represents a reaction against much of the gross materialism of the day. We as physicians must take account of this bald materialism and be careful not to yield too much to it. The great majority of the human race will never face the brutal logic of pure materialism. The true leaders of religion and medicine must guide the popular thought in these matters and not allow the field to remain in possession of moral quacks.

Under the guise of religion, Christian Scientists practically claim an immunity to practise medicine. Magistrate Freschi in the Cole case wisely stated that while the Christian Scientist has the right to believe that he can heal by prayer, he was of the opinion that if he carries and puts that belief into practise for hire and solicits patients by advertisement he exceeds his right as an individual and comes within the province of the law. He further stated that the individual must subordinate his beliefs to the rights of the community when a free exercise of such belief either impairs or endangers the health of the people or tends to place their health in jeopardy. In a few words this well disposes of the religious side of the question.

Physicians must be more careful to stimulate hope and expectation of recovery in addition to employing the proper scientific treatment of disease. An atmosphere of cheer and encouragement is a very great help even in the treatment of grave organic disease and may be all that is required in many simple ailments.

In imaginary, functional, or quickly limited diseases that cannot affect others, I do not believe that most physicians will quarrel with suggestive healing of any kind, with or without an invocation to the Deity, so long as it confines its shadowy ministrations to neurotic men and women who wish it and can be affected by it. When it comes to infectious diseases and helpless children it is time to call a halt.

51 West Fifty-first Street.

THE ADEQUATE TREATMENT OF GONORRHEA.*

By THOMAS WRIGHT JACKSON, M.D.,

Fort Hunt, Virginia,

Medical Reserve Corps, U. S. Army.

In the great increase in popular interest concerning the control and prevention of venereal diseases, as indicated by the actions of medical, religious, and secular bodies everywhere and by expressions in the religious and medical press, as well as in the popular magazines and secular prints, we take great hope for the betterment of social conditions in this country. The dangers to health and happiness, to youth and posterity, from existent conditions can hardly be exaggerated and all measures, direct or indirect, which tend to lessen and remove these dangers demand our warm support. In the army and navy the problem is just now receiving the most serious and practical attention with, as we believe, most favorable promise.

*Permission to publish granted by the Surgeon General, U. S. Army.

In the study and consideration of army statistics, however, it should be remembered that the constantly non-effective rate for venereal diseases (at least for gonorrhea) is not identical with the rate of venereal incidence, by any means, and that in fact there is no true index of the rate of incidence deducible from the reports of sick and wounded alone, as the names of men capable of performing duty need not appear upon these reports, even though daily treatments at the dispensary or hospital are being accorded to them. For example, the constantly non-effective rate of 7.72 per thousand men* should not convey an impression as to the total number of cases occurring in the Department of the East during 1910. The report of the Chief Surgeon, Department of the East, for 1910, states that the "plan of antivenereal campaign consisted in instruction, inspection, and prevention." As a subheading under "prevention" I would mention "adequate treatment of gonorrhea," and it is with reference to this topic only, its difficulty and its necessity, without casting disparagement upon any scheme, movement, device, or measure now under way to lessen venereal disease, that I wish to speak, "lest we forget," in our zeal as publicists, something of our duty as practitioners of the healing art.

No medical officer of the army or navy can fail to secure a wide and extended experience in the treatment of gonorrhea in the public service. Until such time as he attains rank giving him administrative duty only (and frequently long after promotion to such rank) he is sure to have the personal treatment or supervision of a large number of cases of this disease, and I know of few professional positions which afford the experience in venereal and genitourethral diseases which the military and naval service brings to its surgeons. At home or abroad, on land and sea, in barracks or under canvas or nipa thatch in distant frontier provinces of the Orient, there is always abundant venereal practice for the surgeon and unlike his professional brother in civil life he may not decline to treat this particular class of cases because, perchance, he finds the work uninteresting or esthetically distasteful. In the large general hospitals of the service, at recruit depots, or on transports his cases of gonorrhea may constantly number from twenty-five to fifty.

My experience in the service, which is by no means peculiar or unusual, has literally called me to the treatment of hundreds of cases of gonorrhea, in and out of hospitals, in the United States and abroad. Two years ago, in association with a fellow medical officer, I ministered unto the venereal ailments of a regiment of colored soldiers for seventy-five days aboard a transport en route from Manila to New York via the Suez Canal. Perhaps forty or fifty cases were treated daily at sea and in port and the ethnological origin of many of these cases was sufficiently varied to delight the most cosmopolitan practitioner. Malay, Negro, Caucasian, and Mongolian gonorrhea, with all possible blendings of the strains of Neisser's organism from the seaports of the Philippine archipelago, the Malay peninsula, Ceylon, Arabia, Egypt, and the Mediterranean, went to make up our clinical material.

At this time the excellent prophylactic system now in general use in both army and navy was not compulsory, nor indeed was it actually practised upon this voyage, but restriction of shore liberty

*Report of the Chief Surgeon, Department of the East, for 1910, to Surgeon-General, U. S. A.

for those infected and under treatment, with systematic weekly physical inspections of the entire command and compulsory treatment of the infected brought us into New York harbor with a fairly creditable record as to symptomatic cures. The method of treatment employed was that of irrigations with potassium permanganate solutions of varying strength, and considering the difficulties attendant upon the daily treatment of this large number of men in somewhat cramped quarters between decks, much of the time in a rough sea, the record of our floating venereal clinic must be considered good. It was impossible, however, to use the method of microscopic search for the gonococcus in determining the fact of cure in every case and I doubt not that subsequent relapses occurred among the cases reported as cured.

These remarks are intended to call attention to the fact that the combined experience of all surgeons of the army and navy called upon to treat gonorrhea would afford much valuable information if recorded and analyzed. Personally I am forced by observation to the conclusion that we still lack a generally applicable, reasonably dependable method of treatment which does not require months for the cure of gonorrhea.

I desire to submit a report of fifteen cases of gonorrhea observed, treated, and apparently cured at this station during the past eighteen months, together with a brief analysis of the treatment methods, and values. This number includes all the cases of gonorrhea observed here during this period with the exception of two recent cases, still under treatment, and a few symptomatically cured cases whose records as to the presence and disappearance of the Neisser organism and as to details of treatment are, for various reasons, incomplete. The subjective and purely symptomatic observations in these few cases are not deemed of equal and similar value with the recorded microclinical observations and hence are excluded, although every patient is believed to be cured of his infection.

The tabulated record herewith is obtained from three sources, viz., a record of venereal diseases, a record of laboratory observations made, and the official sick and wounded report of the post. All observations in this series were personally made by the reporter. No very startling or impressive responses to treatment are to be noted in this series. To me the most gratifying phases of the matter have been (1) the ultimate cure of every case (apparently), (2) the comparatively small number of complicated cases (arthritis, prostatitis and abscess, epididymoorchitis and urethral stricture being infrequent or absent). Urethral stricture was recognized in but one case, and while posterior urethritis doubtless occurred in a few cases the percentage rate of occurrence was certainly not greater than normal. Keyes gives this rate as 10 per cent. or less for office cases treated by repressive measures (subjective symptoms only considered) and a varying percentage up to and exceeding 50 per cent. for other classes of cases, the presence of pus in the second flow of urine being taken as a criterion.

Duration.—In the cases here reported all individuals were considered as suffering from the disease so long as the Neisser organism was demonstrable either in the discharged urethral secretion or in the exudate or secretion obtained by gently drawing a sterile platinum loop over the exposed urethral mucosa within half an inch of the external meatus. Applying this test for cure, the average duration in this series appears at first sight to be abnormally high, but when we consider that this test is not usually applied in pronouncing cures and when we consider also the fact that a number of the cases here recorded were symptomatically cured long before gonococci disappeared and before treatment was discontinued, the average duration of the disease in these cases need not be considered excessively long.

It must be well known to all medical practitioners that the term "cured gonorrhea" is most improperly and incorrectly applied in a very large percentage of all cases of gonorrheal infection of the urethra. Granting the propriety of the microscopic test of cure, this proposition is too obvious to require argument. It is well recognized by all genitourinary authorities, who frequently call attention to the persistence of gonococci in the urethra and glands of the male patient as well as in the female sufferer, although the persistence is usually considered less intractable in the male patient. While in the female the relationship of suppurative diseases of the utrine adnexa to antecedent vaginal or cervical gonorrhea is generally understood, the fact that suppurative diseases of the bladder, ureters, and kidneys in the male—as well as of the testes, prostate, and epididymis—are frequently the result of ascending infections which were primarily at least plain urethral gonorrheas is less generally appreciated.

While the presence of the gonococcus in unmixed culture in the lesions of suppurative diseases of the kidneys and ureters is not demonstrable in a high percentage of cases, these statistics should not mislead us. There are probably few surgeons of extended experience who cannot recall among their cases of suppurative kidney disease some with definite histories of gonorrhea during years past. And often it will happen that the surgeon has personal knowledge of the preceding urethral infection, having treated the patient therefor in months and years gone by and having observed the upward progress of the disease. Under such circumstances the failure to identify the gonococcus in the lesions of a suppurating kidney or other organ will not be convincing evidence to the surgeon that the infection is an idiopathic one, or one due to infection from pyogenic organisms circulating in the blood stream. Moreover, the autopsy and dissecting tables too often disclose the melancholy story of ascending disease of the genitourinary path arising from an initial gonorrhea.

All injections were made with glass syringes of 10 c.c. capacity except in the case of argyrol. Solutions of this drug were instilled into the urethra with medicine droppers, the injections averaging 2 c.c. All injected solutions were retained in the urethra for five minutes. Irrigations were made with an apparatus consisting of a glass funnel and rubber delivery tube fitted with an urethral tip. All irrigating solutions were used warm. Formula for astringent "a"—Phenol, 0.325 gram; zinc sulphate, 2 grams; bismuth subnitrate, 4 grams; distilled water, 120 c.c. Formula for astringent "b"—Alum, 10 grams; phenol, 2 grams; distilled water, 500 c.c. The total number of cases receiving argyrol was 9; iodine, 8; silver nitrate, 3; astringents, 7, and boric acid, 1. The shortest case treated with argyrol only was fourteen days. The next shortest case (2) treated with iodine only was twenty-eight days. The next shortest case (3) treated with iodine only

Name.	Duration.	Complications.	Relapses.	Where Treated.	Result.	Clinical Type.	Treatment.
1. M.	84 days	None	None	As out-patient and in hospital 11 days	Cure	Moderate Severity	Argyrol, 20 per cent. injection t.i.d. for 30 days Astringent injection "a" for 54 days. (See formula for "a")
2. A.	93 days	None	None	Out-patient	Cure	Moderate Severity	Argyrol, 20 per cent. injection t.i.d. for 47 days Astringent injection "b" for 46 days. (See formula for "b")
3. R.	64 days	None	None	Out-patient	Cure	Moderote Severity	Argyrol, 20 per cent. injection t.i.d. for 7 days Astringent injection "a" t.i.d. for 3 days Argyrol, 10 per cent. t.i.d. for 54 days
4. E.	154 days	None	2	Hospital 51 days and out-patient	Cure	Severe	$AgNO_3$ injection, 1 per cent. t.i.d. for 21 days Astringent injection "a" t.i.d for 38 days Irrigation of urethra, with iodine solution, 1:500, for 95 days
5. S.	46 days	None	None	Out-patient	Cure	Moderate Severity	Irrigation with 1:1000 $AgNO_3$ solution t.i.d. for 32 32 days Astringent injection "a" for 14 days
6. McC.	119 days	None	None	Out-patient	Cure	Moderate Severity	Argyrol, 10 per cent. injection, t.i.d. for 30 days Astringent injection "a" for 89 days
7. S.	68 days	None	None	Out-patient	Cure	Moderate Severity	$AgNO_3$, 2 per cent. solution, injected t.i.d. for 68 days
8. W.	110 days	Epididymo-orchitis	1	Out-patient and in hospital for 6 days	Cure	Severe	Astringent injection "b" for 28 days, t.i.d. Iodine irrigations, 1:500, t.i.d. for 44 days. Argyrol 20 per cent. for 6 days and 10 per cent. for 10 days, t.i.d., by injection
9 M.	60 days	None	None	Out-patiert	Cure	Moderately Severe	Iodine irrigations—1:500, t.i.d. for 30 days. Saturated solution boric acid by injection t.i.d., for 30 days
10. C.	28 days	None	None	Out-patient	Cure	Moderately Severe	Iodine irrigations, 1:500, t.i.d. for 28 days
11. S.	147 days of treatment, covering period of 205 days	Stricture	3	Out-patient	Cure	Severe	Argyrol, 10 per cent. for 20 days,t.i.d. Iodine irrigations, 1:500, for 20 days and 1:250 for 9 days, t.i.d. Argyrol, 20 per cent. t.i.d. for 98 days
12 K.	145 days	None	Hospital for 13 days, then out-patient	No relapses	Cure	Moderately Severe	Iodine irrigations, 1.1000, t.i.d. for 60 days. Argyrol, 20 per cent. t.i.d. for 68 days. Daily alternations of iodine 1:500, and argyrol, 20 per cent. for 17 days
13. D.	34 days	None	None	Out-patient	Cure	Moderately Severe	Iodine irrigations, 1:500, t.i.d. for 34 days
14 E.	14 days	None	None	Out-patient	Cure	Mild	Argyrol, 20 per cent. t.i.d. for 14 days
15 M.	74 days	Epididymo orchitis	None	Out patient and in hospital for 29 days	Cure	Severe	Iodine irrigations 1:500, for 15 days, t.i.d. Argyrol, 20 per cent. t.i.d. for 48 days

was thirty-four days. The average duration of fifteen cases was 82.6 days. The average duration of twelve uncomplicated cases was 75.75 days.

It is recognized that fifteen cases constitute a small number from which to draw conclusions of any kind. However, an analysis of fifteen observed cases, absolutely controlled during treatment and carefully checked thereafter, may mean more than a much larger number where the control, through unfavoring circumstances, has not been absolute and where the criterion of cure is not the one here employed, viz., microscopic search for the gonococci. All the patients in this series were restricted to the post limits during treatment and were effectually cut off from alcoholic or sexual indulgence. Whenever in the surgeon's judgment the violence of symptoms so indicated, these men were excused from all duties or from such activities as drill, fatigue duty, and athletics. Admission to the hospital was accorded to patients whose symptoms or general condition seemed in any way to demand or suggest the need therefor. In addition to local treatment in these cases, hospital patients had the benefits of rest in bed and dietary supervision and they received hexamethylenetetramine (urotropin) in 0.6 gram doses three times a day. However, it will be observed upon reference to the tabulations that the recovery of these men was not markedly hastened by hospital treatment; but it should be borne in mind that all treatments of out-patients were made at the hospital and under surveillance of the hospital corps, absence or attendance being reported to the surgeon. It is obvious that in civil life the surgeon cannot exercise this control over his patients and, generally speaking, it is therefore unlikely that the details of treatment, exclusive of hospital and office treatments, are as carefully observed in civil practice. The obstacles to the attainment of a proper state of the patient's mind—which includes an appreciation of the gravity of gonorrhea and the difficulties of successful treatment, nicely balanced by a cheerful, confident hopefulness and a willingness to cooperate patiently—are very great, both in civil and military practice. But in military practice this state of mind, however desirable, is less essential on account of the element of control which the surgeon may exercise. It would appear from the analysis of

the above fifteen cases that the most prompt cures resulted where a single remedy was used, but as a matter of experience I am by no means convinced of this, having frequently observed immediate improvement in obstinate cases upon a change in treatment, either by substitution or combination.

Concerning the treatment of systemic gonorrhea, namely, the blood and lymph stream distribution of gonococci to organs and tissues more or less remote from the genitals, this paper has nothing to do. My experience and observation in the treatment of gonorrheal inflammations of the joints and of chronic prostatic gonorrheas by means of vaccines was not clinically convincing, although striking effects in chronic arthritis, observed principally in the service of others in Manila, were certainly noted in more than a few obstinate cases when autogenous vaccines were employed, opsonic readings being used as indices. In genital gonorrhea I have seldom seen results from vaccine administration which even the most enthusiastic opsonists and vaccinists could point to with confidence. In actual practice, as well as in rational forecasting, the vaccines are most successful in systemic gonorrhea.

The statement that gonococci usually disappear from the urethra in six months and that they exceptionally persist in the male urethra for eighteen months is made by Keyes,* but he admits that the infectiousness of gonorrhea may be indefinite. He further states that it may be a matter of great delicacy to determine persistent infectiousness of a given case, but that as a matter of fact almost all are cured in a few months. I fear that the brief series here reported, as well as my experience with a far greater number of cases than these, does not support this optimistic view.

Schwartz and McNeil,† from total tests of 324 human sera in New York, advocate the complement fixation test in the diagnosis of gonococcic infections. After presenting their tables they state that "it would seem from the foregoing results that the complement fixation test (using a polyvalent antigen) for gonorrheal antibodies will have a definite place in the field of clinical pathology as an aid in differential diagnosis between the various conditions arising from gonorrheal infection and similar conditions due to other causes. In acute gonorrheal urethritis we do not get the phenomenon of fixation. This is probably due to an insufficient absorption of toxins to stimulate the production of antibodies." In chronic urethral infections, according to these observers, the case is different and the reaction is present and dependable. They further state that "the facts at hand, however, seem to us to prove almost conclusively that a positive reaction is an evidence of living gonococci somewhere in the body and if found in men or women supposedly cured of gonorrheal infection of the genitourinary tract should be construed to mean that they are still capable of infecting others through sexual intercourse."

Conclusions.

From observation and experience during the last ten years, far more than from the fifteen cases here reported, I believe the following conclusions are fairly deducible:

1. We unfortunately do not command any drug or system of treatment with which we can reasonably hope to cure gonorrhea of the genitourinary tract in any measure of time less than "months." The occurrence of a few exceptional cases, promptly curable, is admitted.

2. A certain small percentage of cases is practically incurable; *i.e.* certain cases resist treatment to such a degree as to warrant the use of the term "incurable."* My present series, fortunately, does not contain any case of this class, but I have seen a few such infections.

3. A much larger percentage of cases remain indefinitely cured, not because they are incurable but because the patients do not and will not submit themselves to long extended treatment and restrictions.

4. The total number of "indefinitely infectious" cases from these two classes is much larger than is generally supposed. These persons as well as the uncured female sufferers from gonorrhea play a large part in spreading and pepetuating the disease.

5. Admitting its difficulties of application, there is no proper test of cure except the test of microscopic search for the gonococcus. It is not insisted that the method employed in the present series is the only proper one or that it is free from theoretical objections, but practically it is as easily applied and as reliable as any known to the reporter. If microscopic diagnosis is logically necessary a microscopic test of cure is also necessary.

6. From experiments conducted by them, Schwartz and McNeil claim that the results are "highly significant and show that the complement fixation test detects a certain percentage of cases of uncured gonorrhea which escape careful clinical and bacteriological examination." If true this is certainly important and will materially assist us in promoting the adequate treatment of gonorrhea. Whatever its value may be, however, the complement fixation test is not likely to supersede or displace at once bacteriological search for the Neisser organism in genitourethral infections and we should be constant in our efforts to universalize the employment of this test of cure.

7. In my opinion the most cardinal and necessary factor in adequate treatment is persistence in whatever method or variety of local treatment is chosen, until both clinical and microscopic evidences of disease permanently disappear. It is assumed that supervisory control of the patient's dietary, personal habits and liberties is exercised by the surgeon.

CLINICAL NOTES ON CHRONIC PUTREFACTION TOXEMIA OF INTESTINAL ORIGIN.†

By EDWARD E. CORNWALL, M.D.,

BROOKLYN, N. Y.

ATTENDING PHYSICIAN TO THE WILLIAMSBURGH AND NORWEGIAN HOSPITALS; CONSULTING PHYSICIAN TO THE BETHANY HOPITAL.

The following cases, which seem to illustrate the subject of chronic putrefaction toxemia of intestinal origin, are selected for report from a considerable number of similar cases with which the writer has had experience during the last few years.

Case I.—A man aged 47 years, a merchant, was constipated for the past twenty-five years or more, and during that time he had what he called

*The percentage reported by the committee of the American Medical Association is 3 per cent. See *Journal of American Public Health Association*, page 69, March, 1911.

†Read before the Kings County Medical Society, October 17, 1911.

bilious headaches, which occurred at first every five or six weeks, but gradually increased in frequency until, in October, 1910, they became continuous. At that time he also suffered much from dizziness, weakness, and a constant and distressing cough which the usual remedies did not relieve; and his weight, which was usually 154 pounds, fell off twenty pounds. Examination of his urine was negative; his blood pressure was 150 mm. He was given a laxative tablet to take daily until he no longer needed it, which was after about two months, and was put on a diet which consisted exclusively of milk, cream cheese or pot cheese, butter, bread, cereals, potatoes, green vegetables and fruits, with occasional variation to the extent of a simple rice or bread pudding or a plate of ice cream. He was strictly prohibited from eating any animal tissue or broths or soups made from the flesh of animals, or cane sugar, except the small amount in the occasional pudding and ice cream, or dried peas and beans, cooked cabbage and turnips, vinegar or spices. The diet was arranged to supply an average of about 65 grams of protein daily, and to possess a fuel value of between 2000 and 2500 calories. He has kept up this diet to the present time, varying the proportions of some of the articles, particularly the pot cheese, which during the past three months he has taken in increased quantity, and adding a small daily ration (about one ounce) of fat bacon. During a period of forty-nine consecutive days, from August 5 to September 23, 1911, he accurately measured everything which he ate, and during that period the average amount of protein which he took daily was 65.76 grams, of which not more than 3 grams, on the average, was derived from animal tissue, and the fuel value of his diet averaged 2019.78 calories daily. Two days after he began this diet the headache, dizziness and cough entirely disappeared, recovery of strength rapidly followed, and the constipation greatly improved. He ascribes the improvement in his constipation largely to raw cabbage, which he took in the form of coldslaw twice daily. He gradually regained his lost flesh and is now within seven pounds of his normal weight. His appearance is good, and he says that his muscular endurance is better than it has been for several years, though he does not feel as energetic as formerly.

In connection with this case the following interesting facts are noted. Although the bowel movements have become normal in frequency, the stools undergo changes in appearance during every five or six day period: they gradually get lighter, until on the fifth or sixth day they become a light yellow, and at that time the patient experiences dizziness and a slight palpitation of the heart. When he first notices these symptoms he takes one teaspoonful of magnesium sulphate in a half tumblerful of hot water on going to bed, and the stools become normal and the dizziness and palpitation disappear, until the cyclic disturbance again manifests itself. If he does not take this small dose of salts every fifth or sixth day the stools become slightly loose, with hard lumps in them, and the dizziness is replaced by a headache. If the salts are taken in the morning the dose required is larger and it is less strikingly effective. An examination of the urine made at the time when the dizziness and palpitation suggested a cyclic accumulation of toxins in the blood was as follows: specific gravity, 1026; no albumin; no sugar; no acetone; indican normal. This is interesting in view of the importance so generally ascribed to the degree of indicanura as an index of putrefaction toxemia. Equally interesting and more helpful in making the diagnosis is what happens when the patient eats a small piece of meat, which he has done only three times in the past year: he has a prompt recurrence of the cough and dizziness.

Case II.—A man of 59, a floorwalker, had occasional headaches since he was sixteen, and during the past five years he had a continuous headache. He says he got up with it in the morning, went around with it all day, and went to bed with it, and when he was asleep dreamt that he had it; and often when walking across a room suffered so intensely from it that he feared that he would collapse. He had what was diagnosed as meningitis twenty-five years ago, but recovered from it entirely. He had always been what he considered a moderate eater of meat, but had been an excessive eater of sweets. Physical examination: Appearance healthy, weight 160 pounds, heart slightly enlarged, faint systolic murmur heard over aortic area, aortic second sound impure; examination of urine negative, blood pressure 150 mm. I prescribed for him an exclusive diet, consisting of specified quantities of milk, cereals, bread and butter, milk soups, cream cheese, olive oil, fat bacon, and fresh fruits and vegetables with certain exceptions. I allowed relaxation of this diet to the extent of a small portion of meat twice a week. All animal tissue, with the exception of the relaxation mentioned, and cane sugar were rigidly prohibited, as well as vinegar, spices, and dried peas and beans. This diet was arranged so as to supply a daily average of 65 grams of protein, of which less than six per cent. should be derived from animal tissue, and to possess a fuel value of about 2000 calories. After four days of this diet there was a marked diminution in the intensity of the headaches, and at the end of a week they were entirely gone; and at the end of three weeks the patient reported that in that period he had been entirely free from them with the exception of one slight recurrence which was of slight duration.

Case III.—A woman aged 30 years, a school teacher, suffered for a number of years from occasional severe headaches, which during the last year occurred as often as several times a week; they were sometimes frontal, but the pain usually shifted to different parts of the head; and when they were present her face looked drawn and pale; her mind was dulled, and she found it difficult to attend to her work, and she often felt drowsy during the day. She was habitually constipated and suffered from gastric dyspepsia. She had always been a hearty eater, especially of meat and soups. She had noticed that a saline purge made her feel better. She had been treated for anemia and malaria without success, and her eyes had been tested and found normal. There was nothing in her case to suggest any gynecological disorder. Her weight was 137 pounds; her blood pressure was 118 mm; examination of her urine was negative. I prescribed for her an exclusive diet consisting of milk, in any form, preferably lactacidized, cereals, bread and butter, honey, milk soups, and vegetables and fruits with certain exceptions, allowing relaxation twice a week to the extent of a small portion of flesh food. This diet was arranged to supply about 60 grams of protein daily, of which not more than five per cent, on the average, was to be derived from animal tissue, and to possess a fuel value of 1800 to

2000 calories. After a few weeks of this diet her headaches entirely disappeared, and her mental and physical condition became apparently normal. Further relaxation of the diet was made to the extent of allowing a small portion of animal tissue or eggs four times a week and an occasional simple pudding. Three months later the patient reported continued good health, and ten months later she again reported continued good health.

Case IV.—A woman of thirty, well nourished but sallow, suffered for a year or more from general debility and frequent and distressing headaches. Her eyes were examined and found normal. Examination of her urine was negative. I put her on an exclusive diet of milk, cereals, bread and butter, milk soups, olive oil, and fruits and vegetables with certain exceptions, arranged to supply 60 grams of protein daily and to possess a fuel value of 2000 calories. After three weeks of this diet she reported that the headaches were entirely gone, and that she "felt like a young girl."

Case V.—A woman of thirty-five, weighing 206 pounds, suffered during the last two years from severe palpitation of the heart from slight emotional causes, shortness of breath on moderate physical exertion, and insomnia. She was also irritable and easily disturbed by little things, which is not according to her natural disposition. She had always been a hearty eater, especially of meats and sweets. Her blood pressure was 165 mm, and examination of her urine showed a slight trace of albumin.

I prescribed for her an exclusive diet of milk in any form, preferably lactacidized, cereals, bread and butter, selected fruits and green vegetables, milk soups, honey, occasionally fat bacon, and once a week a small portion of flesh food. This diet was arranged so as to supply 65 grams of protein, of which not more than three per cent. should be derived from animal tissue, and possess a fuel value of 2500 calories. Two weeks later she reported that the heart symptoms had disappeared, that she was feeling much better in every way, and that her husband had noticed a great improvement in her disposition.

Case VI.—A man aged 35 years, well nourished, of healthy appearance, who had always felt well, was rejected by an insurance company because sugar was found in his urine. I also found a trace of sugar in his urine, which had a specific gravity of 1033. His blood pressure was 155 mm. There was nothing in his previous history to suggest disease except that he had always been a hearty eater, especially of meat. I put him on a diet of milk, cereals, bread and butter, selected fruits and green vegetables, olice oil, bacon, milk soups—in fact, an antiputrefactive diet—with relaxation to the extent of a small portion of flesh food twice a week, the diet being arranged to supply a daily average of 70 grams of protein, of which not more than five per cent. was to be derived from animal tissue, and to possess a fuel value of 2500 calories. After he had taken this diet for two weeks I examined his urine, and found that he passed 41 ounces in twenty-four hours, of a specific gravity of 1019, and containing no sugar. His blood pressure at the same time was 118 mm. Six weeks later, while he was still continuing the same diet, his urine and blood pressure were again examined, with similar results.

Case VII.—A boy aged four years, who had been constipated and colicky from his birth, suffered during the past two years from frequent attacks of fever, accompanied usually by gastrointestinal disturbance. A dose of castor oil always seemed to hasten his recovery from these attacks. He was moderately well nourished, but pale and flabby in appearance. I put him on an exclusive diet of milk, cereals, carefully selected fruits and vegetables, old bread and butter, and fat bacon. For six months after beginning this diet he was free from the attacks of irregular fever and gastrointestinal disturbance; then a piece of Thanksgiving turkey brought on a relapse. Shortly after this relapse he had an attack of grip with otitis media. He recovered, kept strictly to the diet, and up to the present time, ten months later, has been free from the attacks and better than he has ever been before in his short life.

Case VIII.—A commercial traveler, aged 49 years, had just recovered from an attack of acute gout in the great toe joint, which was his first attack of that disease. His urine showed a small amount of albumin and a low specific gravity. His blood pressure was 150 mm. His complexion was muddy. For more than a year before he had suffered from occasional insomnia, a tired feeling in the morning, headaches, cardiac unrest and palpitation, especially when smoking, and some general debility. He had been for years a moderate smoker and drinker, and a hearty eater, especially of meat. I absolutely prohibited him from using alcohol and tobacco, and put him on an exclusive diet of milk in any form, preferably lactacidized, cereals, bread and butter, milk soups, olive oil, honey, fat bacon, selected fruits and vegetables, weak tea and coffee, and once a week a small portion of flesh food. The diet was arranged to supply an average daily ration of about 65 grams of protein, of which not more than five per cent. was to be derived from animal tissue, and to possess a fuel value of about 2200 calories. He has followed this diet to the present time, even when traveling, and feels very well.

Case IX.—A man of 45, a clergyman, suffered during the past ten years occasionally from severe headaches, which he had noticed were worse in February. During the past year the headaches were severer than before and more frequent, and occurred with particular regularity and severity every Monday, and his energy and capacity for work progressively diminished. He was constipated, and frequently suffered from gastric and intestinal flatulence. He had always been a hearty eater, particularly of meat and soups. Physical examination showed him to be of large frame, well nourished, somewhat pale; the left ventricle of his heart was slightly enlarged and his aortic second sound was accentuated; his blood pressure was 220 mm; and his urine was of low specific gravity and showed a trace of albumin. I put him on an exclusive diet of milk in any form, cereals, bread and butter, selected fruits and vegetables, honey, fat bacon, cream cheese, milk soups, and once a week a small portion of flesh food, the diet being arranged to supply an average daily ration of about 85 grams of protein, of which not more than three per cent. was to be derived from animal tissue, and to possess a fuel value of 2500 to 3000 calories. On this diet he rapidly improved, and since beginning it has had only one headache, which, it is significant to note, was made worse by a small dose of nitroglycerine. His blood pressure steadily became lower, and after two months was 165 mm, near which point it has remained to the present time, eight months after the beginning of the diet. His urine, examined re-

cently, appeared normal. The patient since taking this diet has experienced not only relief from the headaches, but increased mental vigor, and says that he can do more work with his mind now in one hour than he could before in two; and he also feels stronger physically, especially in the matter of muscular endurance. He says he can walk long distances without fatigue. But he thinks he is less bold and physically enterprising than formerly.

Case X.—A woman aged 24 years, a primipara, showed in the seventh month of her pregnancy a moderate amount of albumin in her urine, with diminished excretion of urea, and a slight edema of the hands, feet, and face. I put her at first on an exclusive diet of milk and cereal gruels for a week, and then on a strict diet of milk in any form, cereals, bread and butter, olive oil, honey, and selected fruits and vegetables, the diet being arranged to supply an average daily ration of about 65 grams of protein and to possess a fuel value of about 2000 calories. The edema soon disappeared and the output of urea improved, though the albuminuria persisted until four months after the child was born. This diet was kept up for one month after the disappearance of the albumin. The infant was nursed by the mother and was remarkably healthy, gaining regularly in weight. The antiputrefactive diet which was given for toxemia of pregnancy proved most suitable for this nursing mother.

Case XI.—A woman aged 45 years, a saleswoman, suffered from universal eczema for about one month. Her entire skin was dark red, rough and infiltrated, and there was considerable bloating of the upper and lower extremities and face. Her urine was diminished in quantity and contained a large amount of albumin. She had pains all over her body. I put her on a rigid antiputrefactive diet, which consisted at first of lactacidized milk, boiled rice and strained orange juice, to which later other cereals and carefully selected fruits and vegetables were cautiously added. Her body was kept anointed with olive oil throughout the course of the disease. Colonic irrigations were given once daily for the first two weeks and then discontinued. For the first eight weeks she was given a dram of phosphate of soda in a glass of water twice a day and a dram of rhubarb and soda mixture three times a day; after that no medication was given. During the first five weeks she ran a slight irregular fever which never exceeded 101° F. At the end of eleven weeks the condition of her skin began to improve, and at the end of thirteen weeks she was apparently well.

Case XII.—A woman aged 75 years was troubled for many years with intestinal indigestion; she also suffered from arthritis deformans which affected the joints of the fingers, all of which were deformed and some of which were immobile. The arthritis deformans was chronic from the start, but exacerbations had occurred. She suffered from frequent and distressing headaches with flushing of the face. There were signs of arteriosclerosis and her blood pressure was 180 mm. Examination of her urine was negative. I put this patient on an exclusive diet of lactacidized milk, cereals, bread and butter, selected fruits and vegetables, with relaxation to the extent of a small portion of flesh food once or twice a week. She kept up this diet steadily for fifteen months, and then, because of symptoms of over-colonization of the intestines with lactic acid bacilli, the sour milk was discontinued for a few months, and resumed later for short periods; otherwise her diet was not much changed, sweet milk and cereals being substituted for the sour milk. The diet was arranged to supply a daily average of about 50 grams of protein, of which not more than five per cent should be derived from animal tissue, and to possess a fuel value of about 1600 calories, but it is probable that she took less rather than more than the prescribed quantity of food. From the time she began this diet her intestinal symptoms improved, and the headaches became less severe and frequent, and long periods, sometimes as long as two or three months, elapsed without their occurrence. When she first took the lactacidized milk she said "it went right to the spot." Along with the improvement in the intestinal indigestion and the headaches, but unnoticed at first, was an extraordinary improvement in the condition of the affected joints. The enlarged joints diminished in size so that the present enlargement is not more than two-thirds or one-half of what it was, except in regard to the nodes of Heberden, which are unchanged, and the remaining masses to a considerable extent have become soft and pulpy, and motion has been restored to the joints in which it had been lost.

The dozen cases which I have here reported showed the following conditions: Severe and frequent or continuous headaches, mental and physical debility, neurasthenia, functional disorders of the heart, irritative cough, glycosuria, severe chronic universal eczema, toxemia of pregnancy, arthritis deformans, irregular fever, cardiovascular disease, and nephritis. In all these cases the administration of a diet which diminished the production in the intestines of the poisons due to the action of the saprophytic bacteria on animal protein, and at the same time relieved the liver and kidneys from unnecessary work, was followed promptly by recovery or great improvement—recovery or improvement which could not altogether or in large measure be ascribed to the drugs given. The beneficial results of this dietetic treatment were, on the whole, so striking that they suggest the general conclusion that chronic putrefaction toxemia of intestinal origin causes or aggravates a large number of common and important morbid conditions.

In considering this subject of chronic putrefaction toxemia of intestinal origin it must be borne in mind that the poisons resulting from intestinal putrefaction are found regularly in the blood of healthy people. This is a necessary consequence of the fact that a certain percentage of the animal protein which gets into the intestines in ordinary conditions of health and diet always falls a prey to the ever-present bacteria of putrefaction. Tappenheimer estimates the proportion of the ingested animal protein which thus rots instead of being dissolved by the digestive enzymes, to be one-tenth, and Macfadyen, Nencki and Seibert estimate it to be one-seventh. This normal or physiological putrefaction toxemia is not necessarily harmful, for the healthy body is so constituted as to be able to withstand it in ordinary conditions. It is only when this toxemia is excessive, or relatively excessive, that it acquires pathological significance. The absolute amount of these putrefaction poisons present in the blood depends on a number of factors, of which the following appear to be the most important: (1) The quantity of putrefiable protein which gets into the intestines: most of this is taken in through the mouth, but some is supplied by the secretions in the intestines and the detritus from

the walls of the alimentary tract; (2) The number, character and activity of the saprophytic bacteria in the intestines; (3) The extent to which the contents of the intestinal tract are alkaline, for these bacteria are active only in an alkaline medium; (4) The length of time during which the intestinal contents are exposed to the action of these bacteria; (5) The condition of the intestinal mucosa, whose walls, when healthy, possess a considerable antitoxic power, and which, when congested or eroded, permit absorption of putrefaction poisons without proper modification; (6) The functional activity of the liver, which is the chief defender of the body against these poisons, and which, if we can apply to men the conclusions suggested by Biot's experiments on dogs, is capable of destroying two-thirds of the poisonous products of intestinal putrefaction which are brought to it in ordinary conditions; (7) The activity of the ductless glands, which there is reason to believe possess an antitoxic function; (8) The activity of the eliminative organs, chiefly the kidneys, by means of which the remnant of these poisons which escape destruction by the natural defenders of the body is finally eliminated.

Variations in the absolute amount of this putrefaction toxemia in any given case naturally follow changes in these factors. Thus it is increased by an abundant flesh diet, gastric, and intestinal dyspepsia, constipation, dilatation of the stomach, enteroptosis, diseases of the intestinal walls, chronic appendicitis, and diseases of the nose and throat which contribute to the supply of putrefaction bacteria swallowed. It is also increased by anything which diminishes the functional power of the natural defenders of the body, particularly of the liver; and by anything which lessens the functional ability of the eliminative organs, notably of the kidneys. The combination of several of these factors may produce great increase of putrefaction toxemia over the normal. For example, a diet containing abundant flesh food combined with renal insufficiency can cause an accumulation of these poisons in the blood sufficient to excite uremic symptoms; and a liberal flesh diet combined with chronic constipation or hepatic insufficiency can easily maintain a degree of putrefaction toxemia capable sooner or later of producing pathological results, particularly in persons whose tissue resistance is low. The pathological results of chronic putrefaction toxemia seem to depend less on the absolute amount of the toxins in the blood than upon the relationship of any given amount to the tissue resistance of the individual: the individual tissue resistance is the relative factor which determines the pathological degree of the toxemia, and it varies greatly in different persons and in different conditions: the amount which is normal and harmless for one person in a particular condition apparently produces pathological results in another in a similar condition. Some people seem able to eat excessive quantities of meat and cane sugar all their lives, and at the same time to violate most of the laws of hygiene, and yet reach a good age, while others, eating and acting in the same way, or even much more carefully, develop Bright's disease, or cardiovascular disease, or diabetes in their fifth or sixth decade.

The diagnosis of chronic putrefaction toxemia of pathological degree and its identification as the cause or aggravator of existing morbid conditions in any particular case can usually be made by clinical means alone, and particularly by the therapeutic method. The therapeutic method of diagnosis consists in giving an antiputrefactive diet in any suspected case and watching results. If recovery or great improvement follows, especially when in this particular case or similar ones treatment by drugs or other agencies has failed to produce such favorable results, the diagnosis is confirmed with a reasonable certainty. This therapeutic method of diagnosis has the advantages of facility of application and absolute safety, and it is on the whole more satisfactory than any of the laboratory methods now at our command: even the most exact of the laboratory methods, which consist in finding the toxic coefficient of the patient's blood, or the aromatic coefficient of his urine, can only give an index to the absolute quantity of toxic substances present, and tell nothing of the relation of this absolute quantity to the tissue resistance of the patient, which is the essential fact in the diagnosis.

The practical question here arises, what constitutes an effective antiputrefactive diet? In the case reports already presented I have suggested in outline the antiputrefactive diet which I use with my own patients. That diet is extremely simple and easy to prepare, and it has proved successful. Other diets equally effective can no doubt be devised without difficulty, provided the essential requirements of an antiputrefactive diet are satisfied. The essential requirements of such a diet are: To reduce the putrefiable protein ingested to a rational minimum, that is, to a minimum which fits the particular case; to keep the contents of the intestinal tract acid throughout; to diminish greatly the amount of cane sugar in the diet or to eliminate it altogether, to be sufficiently laxative to insure a bowel movement once daily, and to restrict the total quantity of food to the needs of the body. The first requirement is met by reducing to a very moderate amount or to zero all protein in the diet which is of animal origin except milk, which is not ordinarily putrefiable because it is protected by its lactacidifiable carbohydrate. The second is met by including abundant milk and cereals in the diet; and if in addition to the lactacid bacilli normally present, we artificially colonize the intestines with extra quantities of those bacilli introduced with the milk or otherwise the acidification of the bowel contents is greatly facilitated: the cereals supply sugar in the lower part of the intestine out of which those bacilli can make lactic acid, which is the great acidifier of the bowel contents and our most direct antiputrefactive agent. The third requirement, to cut out cane sugar from the diet, depends for its sanction on the tendency of that in other respects desirable food to ferment in the alimentary tract and disturb digestion. The fourth requirement, to be sufficiently laxative to insure a bowel movement daily, is directed against that colonic stasis which favors so powerfully the production of putrefaction poisons. The fifth requirement, to limit the total amount of food to the needs of the body, has for its reason the advisability of making as light as possible the necessary work of the liver and kidneys, so that those organs can devote their fullest energies to neutralizing and eliminating the putrefaction toxins to which the tissues are intolerant.

Besides these essential requirements we have to consider, in prescribing an antiputrefactive diet for a particular patient, the indications and contraindications offered by his general condition and by special diseases which may be present. In some cases

it is sufficient to reduce the putrefiable protein to a moderate amount; in others it must be cut out of the diet altogether; in some the restriction of the total amount of food to the needs of the body should be as close as possible, while in others more latitude may be allowed: in young persons and those without demonstrable organic disease considerable latitude may often be allowed, provided the articles of food are appropriate; in older ones who have cardiovascular disease or nephritis, the total quantity of food should be closely restricted. The influence of habit is entitled to some consideration, especially in regard to the articles of food; it is not always advisable to put on an absolutely fleshless diet an elderly person who has been an extravagant eater of meat all his life; though such an one often accommodates himself to small and infrequent rations of flesh food, or even absolute deprivation of it, after having experienced the benefits of the more rigid diet; this is particularly the case when chronic nephritis is present.

Just what constitutes the minimum quantity of food necessary to maintain health, that is, the minimum amount of protein, and the lowest caloric requirement, I do not know, but clinical experience inclines me to the opinion that it is considerably less than what the standard text books on diet assert. In my antiputrefactive diets I rarely give more than 65 grams of protein per diem unless the patient is extra large; and the calories I regulate according to the body weight, the age, the amount of work to be done, and the temperature: a man working hard in cold weather might require thrice as many calories as one lying in bed in a warm room. In chronic putrefaction toxemia the regulation of the fuel ration is not of such precise importance as the regulation of the protein ration; a few extra calories do little harm if they are derived from articles which do not disturb the alimentary tract or the liver. If the patient is obese I usually scrimp the calories, and if he is emaciated I am generous with them.

In arranging my antiputrefactive diet I usually rely chiefly on milk, bread and cereals for protein, and secure extra calories from butter, olive oil, fat bacon, the starch of the roots and other vegetables, the sugar of fruits and honey, and milk sugar. One quart of milk, 12 ounces of cooked cereal, and six slices of bread, will give about 55 grams of protein and 1,300 calories. The vegetables, fruits, butter, bacon, etc., given to bring the calories up to between 2,000 and 2,500, will add enough protein to make the total of that food element about 65 grams. If more protein is required I increase the milk or cereals, or add cheese, or allow a small quantity of animal protein; in many cases of putrefaction toxemia a small portion of meat, fish, poultry or eggs can safely be allowed once to four times a week; and if such a relaxation of the diet increases the protein too much the milk, cereal or bread can be diminished to make the protein ration balance. Vegetables and fruits, though poor in protein content and of small fuel value, have an important place in an antiputrefactive diet because they supply necessary salts, add variety to the diet, which is often monotonous to the patient, relieve constipation, and are "filling."

The limitations of this paper forbid extensive discussion of the details of this antiputrefactive diet, but there is one very practical point in connection with it which I must not pass over; it is, how to make the patient take the diet when it is prescribed. For bringing this about I have found the two following precedures effective. First, I explain to the patient at considerable length and with considerable force, the purpose of the diet and how it will accomplish that purpose. A full and forceful explanation usually enlists the patient's interest and secures his cooperation—that is, if he is intelligent, and the treatment of other than intelligent people along these lines is a hopeless task. Second, I write out carefully the diet for each patient, and do it in his presence, stating exactly what things he may eat, with the quantities and the time of eating each thing, and also stating the things which are forbidden. It is not safe to trust anything in this matter to the discretion of the patient, for if it is possible for him to misunderstand any of his directions he may be confidently expected to do so.

I will close these remarks on the subject of chronic putrefaction toxemia of intestinal origin with a general summary of the conclusions to which my studies of that condition have so far led me.

(1). Man's natural diet is a mixed one, derived from both the animal and vegetable kingdoms; and it appears to be a fact that on such a mixed diet, other things being equal, he flourishes best and attains his highest development.

(2). In the normal physiology putrefaction products are regularly formed in the intestines as a result of the action on animal protein of the ever-present saprophytic bacteria. These putrefaction products, some of which possess toxic properties, being soluble, are absorbed into the circulation; a portion of them is destroyed or neutralized by the antitoxic organs of the body, and the remainder, after having produced a putrefaction toxemia, is eliminated.

(3). Putrefaction toxemia, which is a regular and normal occurrence in the healthy body, acquires pathological significance only when it becomes excessive, or relatively excessive.

(4). When this toxemia is excessive, or relatively excessive, either because of too much animal food in the diet, because of abnormal conditions in the gastro-intestinal tract, because of insufficiency of the liver or kidneys or other antitoxic or eliminative organs, or because of low tissue resistance, then it directly produces morbid conditions or aggravates existing ones.

(5). The diagnosis of the pathological complex due to chronic putrefaction toxemia of intestinal origin can be made with ease, safety and reasonable quickness by the therapeutic method, which consists in giving the appropriate treatment in suspected cases and watching the result.

(6). The treatment of this condition is essentially dietetic, and consists in reducing to a rational minimum the amount of putrefiable protein ingested; increasing the amount of lactic acid formed in the lower part of the alimentary tract; eliminating cane sugar and other disturbing articles from the diet; including in the diet articles which are laxative; and reducing the total amount of food to the needs of the body.

Adrenalinemia and Its Determination.—Bröking and Trendelenburg determined with the aid of a delicate frog preparation that the proportion of adrenalin in normal blood is 1 to 2,000,000. This proportion is also found in arteriosclerosis, pregnancy, parturition, chlorosis, and diabetes. There is a diminution of adrenalin in cases of nephritis with hypertension and an increase in cases of Graves' disease.—*Deutsches Archiv für klinische Medizin.*

SOME OBSERVATIONS REGARDING THE CONTROL OF MEASLES.

By PAUL B. BROOKS, M.D.,

NORWICH, N. Y.

HEALTH OFFICER, NORWICH, N. Y.; MEMBER ALUMNI, BELLEVUE HOSPITAL; FORMERLY MEMBER OF STAFF OF BUFFALO STATE HOSPITAL, ETC.

Measles is a disease too well known to require introduction. We have all had experience with it, as our grandmothers had before us. In 1910 there were 70,000 reported cases in New York State alone. In spite of our long and intimate acquaintance with the disease, there are still some mooted points regarding it, notable among which are these: Whence does it spring? Can it be controlled or prevented? As for the etiology, it is safe to assume that it is a bacterial infection, but we know practically nothing of the nature of the organism. Such experiments as have been made in the inoculation of animals with the virus, while of scientific value, have brought us no nearer to the discovery of the organism.

Close observation of some two hundred cases during a recent epidemic led the writer to certain conclusions: First, that the disease is rarely communicated except through the presence of an individual suffering from the disease, and very rarely, if ever, through a third person, clothing or house infection; second, that it is infectious from the beginning of the catarrhal stage, possibly more so than after the appearance of the eruption, and that it is this fact which has rendered ineffective our efforts to control it. To return to the question of the identity of the causative organism, the conclusions above noted regarding the source of communication might lead to the hypothetical deduction that the organism is at least very sensitive to climatic and other influences and will live an extremely short time outside the living host. This susceptibility, if it exists, may help to explain the fact that, as during our recent epidemic, the disease often disappears as if by magic with the arrival of the warm and open summer months.

Can epidemics of measles be prevented or controlled? With 70,000 reported cases, as compared with 8,536 of typhoid, 22,626 of diphtheria, and 31,500 of scarlet fever, and considering the fact that at least a third of the measles cases are not reported, it is a safe assumption that it is not controlled in spite of vigorous efforts on the part of State and local health authorities. Why? In part because the public have not yet become reconciled to the loss of their inalienable right to give measles to their neighbors; but principally because our efforts are directed taward "locking the barn after the horse is stolen." We know that the public school is a fertile breeding ground for epidemics of this and other infectious diseases. A school child, during an epidemic of measles, presents the signs of an ordinary coryza. As "running at the nose" is a symptom prevalent among school children, especially among the poorer classes, the year around, this attracts little attention on the part of parent or teacher. The child goes about infecting every other susceptible child with which it comes in contact for three or four days, or until febrile symptoms, or the appearance of the eruption, call attention to the fact that the child has measles. Then, if a physician happens to be called and the case reported it is put in quarantine, and probably the house is fumigated when all the family have recovered. There is, therefore, a serious "leak" in our system. In short, quarantine and fumigation alone are ineffective. Indeed, as for fumigation, assuming that my previously noted conclusions are based on fact, it is a waste of time and a needless expense. In Norwich it has been discontinued, at least temporarily.

Any system of control, to be effective, must take first account of the cases in the catarrhal stage. It means systematic examination of all school children during an outbreak or, better yet, a daily examination during those seasons in which we can confidently anticipate outbreaks of this and other infectious diseases. Upon discovery of a suspicious case not only should that case be promptly isolated, but an effort should be made to learn, so far as possible, the names of all other susceptible persons who have been exposed, and to have them report for examination daily during the period of incubation. Upon the appearance of the first suspicious symptom each one should be isolated. The most potent arguments against such a system are that it would entail a greater expense than that now in vogue, and that public opinion in regard to the necessity for preventing measles is not sufficiently developed to make cooperation likely.

While the average man resents the application of public health regulations to his own person and affairs, there is a growing appreciation, on the part of the public, of the utter foolishness of being subjected to suffering or inconvenience on account of diseases which could be prevented. Public health measures do not ordinarily excite great public enthusiasm, but a system which could be recommended as giving promise of efficiency would appeal more readily than one offering the inconveniences without the results. Discourses something like this are common: "Doctor, they never used to quarantine and fumigate measles!" "No," and the health officer proceeds to enumerate the dangers attending complications and sequelæ and the excellent reasons which have led to an attempt to control the disease. "But, doctor," your inquisitor continues, "is it not a fact that there are just as many cases now as there ever were?" The reply depends largely upon the elasticity of the health officer's conscience. This is the question which should be settled before we undertake the control of this disease: Is measles sufficiently serious to warrant efforts toward its prevention or elimination? If so, then we might apply that time-worn aphorism "That which is worth doing at all is worth doing well."

Quoting from the Bulletin of the New York State Health Department for January, 1911: "In eleven years of the last twenty-five the deaths from measles have exceeded those from scarlet fever, and their average mortality has been annually 1,100 to 1,350. Taking account of its remote effects, measles is probably fully as large a contributor to mortality as scarlet fever." Aside from all consideration of mortality, there is also to be considered the inconvenience and interrupted school work which it occasions. A hundred cases among school children mean at least a hundred weeks lost from the school year, and in these days of intensive education this alone is a serious matter. It is probably safe to assume that intelligent public opinion would support any reasonable measures which would give promise of eliminating this disease, which is, to say the least, a nuisance.

Conclusions.—The organism which causes measles has not yet been discovered, but, reasoning by analogy, it may be assumed that it lives for a very short time outside the living body. Measles is prac-

tically always communicated through the presence of an infected person; rarely, if ever, through a third person, clothing, or house infection. It is infectious from the beginning of the catarrhal stage. Our present efforts to control it do not give satisfactory results, chiefly because we permit the cases in the catarrhal stage to go undetected. If it is to be controlled or prevented, it must be through isolation upon the appearance of the first symptoms.

THE TREATMENT OF MULTIPLE GLANDULAR TUMORS.*

By RUSSELL H. BOGGS, M. D.

PITTSBURG, PA.

The above form of title presupposes an extreme clinical view of the subject. To the pathologist, it would seem an exceedingly inadequate classification, but the fact is that the diagnosis between tuberculosis of the glands, lues, sarcoma and Hodgkin's disease is never absolute until the case has come to operation or autopsy. However, he who tabulates a series of successful treatments of tuberculous glands will undoubtedly have included a considerable portion of cases which were not tuberculous. It is highly unscientific to apply an exact classification in clinical work, where our knowledge is insufficient to insure accuracy. It is rather striking how similar is the treatment of all these conditions, even if the glands have been excised and a scientific diagnosis made. The best treatment remains the *x*-ray, the best drug either iodine or arsenic, except in syphilis, where we have a specific treatment. It is also noteworthy that tuberculous glands may be well treated with the iodides in spite of the detrimental effect this drug has on pulmonary tuberculosis. I have also been amazed frequently at the beneficial effect of alterative doses of mercury, even in cases where lues could be definitely excluded.

For the reasons just mentioned and for the purpose of describing the treatment, I have given the following clinical classification: A. Large glands, broken down. (1) Tuberculosis; (2) Sarcoma; (3) Glanders actinomycosis; (4) Syphilis; (5) Yaws. B. Large glands, not broken down. (1)Tuberculosis; (2) Hodgkin's disease; (3) Multiple sarcoma; (4) Syphilis. C. Small glands, not visible. (1) Syphilis; (2) Simple inflammatory; (3) Tubercular; (4) Carcinoma.

While the *x*-ray is indicated in all of the glandular diseases mentioned, with the exception of lues, my experience has been that the glands produced by Hodgkin's disease respond quicker to the *x*-ray and also recur more quickly than in any other disease mentioned. A large tuberculous mass of glands will not respond to eight or ten treatments to the same extent as Hodgkin's disease or sarcoma, but after they have responded the result is more permanent. In the patient with Hodgkin's disease, the enlargement can be made to entirely disappear, but usually within a few months after the treatment there will be a recurrence, and it is necessary to keep raying the patient at frequent intervals to keep down the enlargement. In this disease a patient, emaciated and bedridden may by the ray not only show a temporary disappearance of the glands but may even resume his occupation for a time. As soon as any recurrence is noticed, treatment should be administered and, as a rule, the external tumors can be controlled for a long time or until the patient succumbs to deep involvement.

Lymphosarcoma in which the disease disappears under röntgen treatment is slow to recur in comparison to Hodgkin's disease. However, the results do not compare with those in the cases diagnosed as tuberculous glands, but I have patients apparently well for three years in whom a gland had been removed and a pathological diagnosis made. In this connection I will mention the following case:

Mr. H., age forty-two, had a gland removed from the left cervical region at the Mayo Clinic and a diagnosis of lymphosarcoma made. On account of the size of the mass operation was not advised, and they referred him for *x*-ray treatment, stating that it was worth at least a trial. At the end of three months the mass had all disappeared and no glands were palpable. Two years and eight months have elapsed and there has been no recurrence. To be on the safe side a few treatments were given at intervals. To my surprise, last summer, when he came for an examination, he informed me that he had been married lately.

Another patient, aged twenty years, was operated upon for lymphosarcoma of the cervical glands, followed by a recurrence before the wound was entirely healed. The tumor increased under radiation, given three times a week for six weeks, when the recurrence was as large as the original growth. Then intense radiation daily given for two months, after which irregular treatments were given. At present, six months later, there has been no recurrence. The patient's sister, aged sixteen, developed a similar mass in the cervical region, and on account of the other recurrence, *x*-ray treatment was given at once, and within two months the growth had disappeared. In either case sufficient time has not elapsed to say anything except that the primary growths disappeared under *x*-radiation in about the same time and with about the same amount of radiation. This has been my experience in a number of cases diagnosed clinically.

In the tuberculous cases, the severity of the process ranged from large broken down glands and large glands not broken down to glands which were almost invisible. The rapidity of results is most striking in the large glands which were broken down, and it is particularly interesting to note that these cases were just as permanently benefited as in the cases where the glands were only of small size. In comparison to the size of the glands it requires less treatment to reduce the mass, in a tuberculous patient where the glands are large and broken down or about to break down. Strange as this may seem, it is true, but we are unable to account for this, unless it is due to the fact that there is so much more glandular tissue present in the large tumor which is much more easily affected by the röntgen rays. Most likely, there is a constitutional effect, and this is most pronounced when a large amount of tuberculous tissue is rayed, as well as the fact that the tissue is of lower vitality than in the smaller glands. These facts suggest that in the destruction of tissue an autogenous vaccine is set free. Crane claims to have demonstrated an increase of the opsonic index. It has been demonstrated when large tuberculous glands have been rayed that a tuberculous process in other parts of the body will often rapidly disappear. It is a well-

*Read before the Medical Section of the Allegheny County Society, October 19, 1911.

known fact that if a patient, having large cervical glands, is rayed intensely, tubercle bacilli may disappear from the sputum. The marked gain in strength and weight shows there must be a constitutional, as well as a local effect. This is more marked in tuberculous glands than in any other disease mentioned. Possibly this accounts for so much better end results in tuberculosis than in any other glandular disease by radiation.

Radiation is indicated in all enlarged glands that have reached any size, unless produced by an acute inflammatory process. In the earlier cases medical treatment should not be persisted in too long, as there is danger of suppuration followed by scarring. The medical measures can be continued in conjunction with the röntgen rays. The disease in the beginning is often local in the cervical glands, and by waiting there is danger of more extensive involvement. The treatment, to be effective, must be employed by a capable clinician and must be adapted to the individual patient. If the dose is too weak there will be no progress. On the other hand, treatment must not be pushed too far, as it would not be judicious to produce a necrosis or a late degeneration of the healthy tissues. When a patient has a breaking down or suppurating gland this should be incised in order to give free drainage. An excellent method is to swab out the cavity with equal parts of iodine and carbolic acid. It is better in such cases to ray the patient, at first daily, in order to secure a quicker result and get the disease under control as soon as possible. As before stated, the results are so good and permanent that no one should hesitate to adopt this method as a routine procedure in tuberculous adenitis, which does not readily respond to medical treatment. The average case will not derive much benefit until about ten radiations are given. The induration and infiltration will begin to disappear, leaving the surrounding tissue less swollen and the enlarged glands more freely movable. At the end of three weeks the skin usually becomes slightly red, followed by a reduction in the size of the mass, if the proper technique is employed, that is, raying the patient with the tube placed from 12 to 15 inches, passing the rays through a filter with the tube at the proper degree of vacuum and excited by the proper amount of current. It is necessary to make each case an individual study and vary the dosage the same as any other therapeutic agent, in order to produce the desired result. Then treatment, as a rule, is given two or three times a week, and the average case will require from twenty to thirty radiations. When the skin becomes slightly red it is followed by a tanning similar to that of a sunburn, and then a rapid reduction takes place. If the reaction is marked, by the time it disappears one is scarcely able to palpate the remaining portion of the glands. Lymphatic tissue, and particularly the lymphatic channels, are converted into fibrous tissue, thus eliminating entirely the possibility of a spread of the disease. The rays have a selective action for the glandular structure, and if given in proper dosage will destroy the glandular tissue, leaving only the stroma of the gland, and a large amount of this tissue is absorbed, leaving the patient's neck almost normal. Patients when referred early can be cured without the glands suppurating or the breaking down of a single gland, thus entirely avoiding scarring. It is evident that the röntgen treatment is the most effective method of treating tuberculous cervical adenitis in all varieties, because the most permanent and the best cosmetic results can be obtained. While the end results obtained by the röntgen treatment in other glandular diseases are not as uniform and permanent, this method offers as much as or more than other treatment alone or in conjunction with other methods. In view of the futility of all the various methods of treating malignant adenitis, the röntgen treatment offers a better prospect of temporary relief or permanent cure than any other method known at present.

The result in the treatment of lymphatosarcoma by the röntgen rays, if the patient has been referred before the glandular enlargement is too widely scattered, even if the mass has attained considerable size and the skin is not broken, are usually very gratifying, and in most cases the disease can be cleared up under radiation four or five times more intense than is required in Hodgkin's disease. If the skin is broken the same results cannot be expected, as then deep metastasis takes place rapidly. It has been stated that there is danger of the röntgen rays stimulating a malignant process, but this can be emphatically denied when radiation is given intensely and not in small stimulating doses. Intense radiation is never stimulating, even from the beginning, and has a tendency to prevent metastases.

TRANSILLUMINATION.

By A. L. BENEDICT, A.M., M.D.,

BUFFALO,

CONSULTANT IN DIGESTIVE DISEASES, CITY AND COLUMBUS HOSPITALS; ATTENDANT DIGESTIVE DISEASES, MERCY HOSPITAL; AUTHOR OF "GOLDEN RULES OF DIETETICS"; EDITOR "BUFFALO MEDICAL JOURNAL."

This article has been suggested by a very valuable contribution to the Medical Record, November 4, 1911, by Dr. Morris H. Kahn of New York. So much attention has been devoted to *x*-ray penetration, and transillumination has been so largely limited to the scrotum, to the antra of the head and to gastrodiaphany, that it is worth while to call attention to the really great value of ordinary light rays in diagnosis. Opacity is a relative term, as powerful Röntgen rays give very light shadows of bones, and as any bright light will penerate the soft tissues to a considerable degree. Thus, as Dr. Kahn points out, transillumination will enable one to locate an opaque foreign body, in any comparatively thin member, with great exactness.

The bones of the fingers can be inspected by sunlight almost as closely as with *x*-rays. Sunlight is harmless for any ordinary length of exposure, though capable of producing lesions quite comparable with *x*-ray burns from long exposure of parts ordinarily protected by clothing, as any one knows who has had experience with camp and water-side practice. Sunlight requires no expensive apparatus, and is available most of the time. A screen can be improvised from an old derby or soft felt hat, with part of the crown cut out. Anyone inspecting the hand by this means for the first time will be amazed at the distinctness with which the bones can be traced. One cannot hope to detect differences in calcification, imbedded needles, shot, etc, as with the *x*-rays, but deformities, displacements, and metallic bodies in the soft parts can be easily detected. Again, as Dr. Kahn states, splinters and similar substances, transparent to *x*-rays, may be detected by ordinary light, though, as to this, I have no personal experience.

Dr. Kahn cites Voltolini's and Heryng's application of light rays to the detection of diseases of the upper respiratory tract and it is possible that by the use of artificial light of great brilliancy, properly limited, diaphany may prove to be applicable to the chest and abdomen.

In several cases the differential diagnosis between ascites and different forms of abdominal cysts has been in doubt. Using any bright light and a tube of pasteboard, metal, etc., I have in these instances been able to exclude both solid tumors and cysts with more or less opaque contents, such as dermoids, multilocular ovarian cysts, with turbid contents, etc. In two instances the diagnosis has further been limited by auscultatory percussion, etc., to a definite collection of clear fluid, as opposed to fluid loose in the peritoneum. Practically, this means intraligamentous cyst, if the collection is large and of clear liquid. In one case I interrupted an operation for the injection of oxygen into the abdomen, for a supposed tuberculous peritonitis, showing that we had to deal with a cyst of clear contents, which must in all probability be parovarian, and this proved to be the case, materially altering the surgical procedure.

APPENDICULAR ABSCESS FOLLOWED BY PHLEBITIS OF THE EXTERNAL JUGULAR VEIN.

By JOHN H. RICHARDS, M.D.,

NEW YORK.

LECTURER IN GYNECOLOGY, NEW YORK POLYCLINIC; INSTRUCTOR IN CLINICAL PATHOLOGY, CORNELL MEDICAL COLLEGE.

The history of the case is as follows: A young woman aged twenty had a first attack of appendicitis about four years ago. She was treated by the usual medical methods after operation was refused. Since that time I have seen her in six acute attacks. At each time I advised operation, but after each recovery the patient found herself more easily able to make an excuse for the refusal of operation. On December 4, 1910, the last attack occurred. I saw her only once, for the mother telephoned me the next day that she was much better; that her bowels had moved well, and that her temperature was almost normal. The tenderness had not, however, left the appendicular region. About a week later they called me again, and at this time I found a large mass in the right lower abdomen. They consented to operation, so I sent the patient to St. Elizabeth's Hospital, where I operated, making the incision over the mass. I emptied the abscess, and removed a piece of greatly thickened omentum the size of my hand. Not finding the appendix easily, and being unwilling to break up the adhesions about the cecum, I did not remove the appendix and drained the abscess through the wound, sewing up the remainder of the incision. The drainage was free and on the third day following the operation the temperature was normal, and the bowels had moved well. No untoward symptoms developed until the eighth day, when the temperature rose to 105° and the pulse to 140. There was also a chill. The drainage was free and there were no signs of extending peritonitis. The drainage had a fecal odor, but not more so than at the time of the operation, and there was no fecal matter in the drainage. The patient complained of a stiff neck, with soreness in the left side of the neck. I did not pay much attention to this, thinking that she had muscular rheumatism. I called Dr. Bolling Lee in consultation. He advised opening up the wound a little and putting in a larger tube. He did not, however, think that there were signs of extending peritonitis, or other inflammation in the abdomen. On the following day the pain in the neck was much more severe, so I examined this region more closely and found the external jugular hard like a cord, and very painful to the touch. Just above the clavicle there was some perivascular inflammation. I did my best to immobilize the head, and gradually the inflammation disappeared. There was no tenderness at the last visit on January 15, 1911.

I report this case on account of the rarity of the complication. Phlebitis in the leg is common after such cases, but I have heard of none in the external jugular, nor have I been able to find any reports of this condition in the literature.

Medicopsychological Essay on the Causes and Remedies for Criminality Among Children.—H. Dauchez declares that only incorrigible children and those who have been caught repeatedly in crime should have meted out to them the extreme penalty of the law. Reformation is easily obtained under proper treatment if we can get the child to see his responsibility and exercise his will. Society, educators and parents are partly responsible for the fall of these children. The surroundings into which they get, the neglect of parents, the ideas inculcated by an irresponsible press, the inducements offered by wicked persons, all lessen the responsibility of the child, weak and immature, and often neglected by all those influences which should lead him upward. Still we should not forget that every normal child has a responsibility for his acts. Only among idiots, imbeciles, degenerates, those possessed by obsessions and hallucinations, kleptomaniacs and somnambulists, are acts committed for which they are not responsible. The hypothesis that children are born criminal cannot be sustained by scientific observation. In examining these children the physician should always give them the benefit of the possibility that they were led into crime by others, by the contagion of evil, and by the neglect of parents, allowing them to get into improper surroundings. True impulsion, like obsession, is rare in children.—*Archives de Médecine des Enfants.*

The Value of Medicopedagogical Treatment in the Care of Moral Anomalies.—Paul-Boncour says that there can be no doubt of the efficacy of the methods initiated by Seguin of treatment of mentally defective children. Every day the excellent results of this treatment are seen. But in cases of moral anomalies there is some question as to the value of committing such children to an institution with a certain hope of cure. The author believes that we shall get good results in those cases in which the moral anomaly is coincident with lack of mental development, but that in cases of moral anomalies in minds that are normal this treatment is liable to fail. Moral sentiments are not lacking in the mentally defective, they only require development and education; as their motor hyperexcitability is lessened and they become less unstable and impulsive their moral sentiments are increased, they learn to know good from evil, and to think about the results of their acts. There are congenital perversions of morality that do not result from intellectual insufficiency, and these children, while benefited by the regulation of habit, are not cured by it. They are true moral idiots. The creation of institutions for the treatment of young criminals is not going to be the solution of the problem of prevention of crime in all cases. Every case must be individualized and studied by itself.—*Le Progrès Médical.*

THE ETIOLOGY OF ARTERIOSCLEROSIS.

THE knowledge of etiology of such a disease as arteriosclerosis is of more importance from the standpoint of prevention than of cure. Chronic degenerative changes in the walls of the arteries, when manifested by symptoms, are usually of a degree in which restitutio ad integrum can no longer be thought of, and the physician's task must be confined to symptomatic treatment and to the adaptation of the patient's mode of life to the limited function of the circulatory system. It was with the idea of preventive medicine that Max Herz, a well-known heart specialist of Vienna, sent out several hundred inquiries among Austrian physicians in the endeavor to learn the causes of arteriosclerosis, as understood by them. The letters were sent to the men who presumably were situated to study the causes of this condition, namely, the family physicians, who know more of the habits and mode of life of their patients than the specialists in large cities. The results of this method of investigation, reported in the *Wiener klinische Wochenschrift*, November 2, 1911, proved to be quite interesting, some 800 answers having been received by Herz. Of the causes named as productive of arteriosclerosis, without reference to the frequency of such causes, nervous and psychic influences were mentioned in 748 instances, age in 455, alcohol in 451, syphilis in 406, diseases of metabolism in 397, physical labor in 354, tobacco in 339, heredity in 267, food and drink in general in 103, infectious diseases in 104, tea and coffee in 61, and temperature changes in 53. The surprising thing in this table, according to Herz, is the number of answers mentioning nervous and psychic influences in the etiology of arteriosclerosis, for he says that specialists in the diseases of the heart and blood-vessels would not have given a similarly important place to these causes. Yet the opinions of the physicians addressed by Herz were in accord with the popular opinion of "premature age," that is, of arteriosclerosis, and moreover, were quite rational when the great importance of the psychic factor in bodily functions is remembered. The frequency of the other causes mentioned is much as can be expected from such an inquiry, the rôle of alcohol, tobacco, gout, syphilis, etc., in the etiology of arteriosclerosis having been unmistakably shown by clinical observations everywhere.

Herz's figures assume a somewhat different aspect when they are studied from the standpoint of importance of each cause of arteriosclerosis mentioned and not from the number of physicians naming it. Of course, the relative position in the scale of frequency gives this aspect of the etiology of arteriosclerosis, and the answers could be easily grouped into three divisions. Of them, psychic and nervous influences were mentioned first in 150 instances, physical work in 146, age in 138, alcohol in 133; in the second group, tobacco received 88 votes, syphilis 77, heredity 72; in the third group, food and drink in excess in 24 instances, metabolic diseases in 19, coffee and tea in 13, infectious diseases in 4, changes of temperature in 3 instances. Several causes received but scattering mention and cannot be discussed here.

This arrangement of answers is of still further interest, for it shows the great divergence of opinion among practical physicians regarding the importance of the various factors in the etiology of arteriosclerosis. It shows, too, that the active campaign against alcohol and against tobacco, with the usual statements about their importance in the causation of the degeneration of the arteries, has not led Austrian physicians to change their views on the subject. Indeed, many of them specifically remarked upon the rarity of arteriosclerosis in regions where men, women, and children were in the habit of using alcoholic beverages, or where the peasants never let their pipes out of their mouths. On the other hand, such a local arteriosclerotic condition as "intermittent claudication" was in every instance referred to the excessive use of tobacco.

We cannot here further consider Herz's interesting study of the etiology of arteriosclerosis, but it certainly should call forth similar inquiries in other countries, so that the causation of this widespread affection of modern life can be better understood. The pendulum has had its maximum swing in the direction of the study of infectious diseases, and it is time that diseases of metabolism and chronic degenerations, such as arteriosclerosis, recovered their proper place in medical research.

THE INFLUENCE OF IMMIGRATION UPON THE PREVALENCE OF TRACHOMA.

THE Treasury Department ruling that trachoma is a dangerous contagious disease makes deportation mandatory in the cases of all aliens who are found to be suffering from this affection at the time of their landing in this country. In view of the fact that there has been lately considerable agitation of this question, and that many men in the profession have stated that they believe the contagiousness has been greatly overestimated, and that some pressure has been brought to bear upon the federal authorities to reclassify the dangerous contagious diseases with a view of removing trachoma from the list, a consideration of the attitude toward this same question of the renowned eye specialists of other countries than our own is timely and worthy of note.

In the *Crónica Médico-Quirúrgica* of Havana for September, 1911, there is an article entitled, "New Considerations of Trachoma in Cuba," by

Dr. Juan Santos Fernandez, in which the author presents the results of his experience with this disease for the last thirty-six years. He still has under observation cases which he saw for the first time in 1875. In common with most ophthalmologists he recognizes two principal forms of the disease—the "granulosa" or follicular type, which is comparatively easy to cure, and the type which presents more deep-seated changes in the conjunctiva, and which he considers practically incurable. Although from the standpoint of scientific exactness, this last is the only form which merits the name of true trachoma, he nevertheless believes that the difficulties of diagnosis between the two types, together with the fact that the treatment is practically the same for both forms warrants us, in the interest of public hygiene, in retaining the old classification. Out of 36,242 eye affections which fell under his personal observations for the period of 28 years from 1875 to 1903 there were 1881 cases of trachoma, that is to say 3.25 per cent. of all his cases were classified under this heading. Since 1903 the percentage has gradually increased, until in his latest statistical compilation, embracing the period from 1908 to 1910 inclusive, 6.31 per cent. of all eye affections were trachoma. While making due allowance for the increasing tendency on his part to classify doubtful cases as trachoma in the interests of public hygiene, the author nevertheless believes that there has been an actual increase in the prevalence of this disease in Cuba, and he attributes this increase to the changed character of the immigration into that country. Of recent years this has been very much of the same nature and origin as the immigration into the United States and Canada. In common with those countries Cuba has taken legal steps to keep out the immigrant afflicted with trachoma, and, although the author does not believe that trachoma is to be classed as a highly contagious disease, he does believe that it is capable of being spread in this way, and that its dangers fully warrant the enforcement of laws prohibiting its entry into the country.

ACUTE DILATATION OF THE STOMACH IN PNEUMONIA.

Acute dilatation of the stomach is not an infrequent event after administration of an anesthetic in the course of an abdominal operation. The textbooks mention, too, that it sometimes occurs in acute infections or wasting disease, but give no more particulars. Among clinicians pneumonia is certainly seldom thought of as a disease in which this serious complication may occur, yet in the December issue of the *American Journal of the Medical Sciences* M. H. Fussell reports five such instances from his own practice, and collects six others from the literature. Early diagnosis of acute dilatation of the stomach is of such importance for the patient that Fussell does well to call attention to the symptoms and signs observed by him.

Vomiting was seen most frequently, the vomitus being very abundant, frequently of fecal odor. The act of vomiting was painless, much like that of general peritonitis. Pain, of course, depends upon the condition of the patient; in pneumonia delirium frequently masks this symptom. Abdominal distention occurs very quickly and is characteristic because of its situation in the epigastrium, causing an appearance of a "tumor" there; as the stomach increases in size, however, the distention becomes general. Splashing sounds can be usually obtained over the epigastric tumor and occasionally peristaltic waves may be noticed. Collapse is a most frequent and urgent symptom. The patient's face is anxious and pinched, his eyes are sunken, breathing is rapid, and the general appearance is that of approaching dissolution. Of course, conditions simulating this picture, such as general peritonitis, intestinal obstruction, acute hemorrhagic pancreatitis, etc., must be kept in mind and carefully differentiated.

Treatment should be prompt, for delay in this condition is dangerous. Treatment is very simple, consisting of the introduction of the stomach tube and lavage of the stomach, repeated as frequently as distention occurs. Collapse, in this instance, is not a contraindication to the use of the tube, for relief can be obtained only by mechanical evacuation of the dilated stomach. Turning the patient on the right side or on the face is frequently of much use, for it seems that in some instances constriction of the duodenum by the mesentery and its vessels may be the chief etiological or, at least, a contributory factor. Stimulation of the patient may, of course, be required, and all mouth feeding must be stopped for some time.

The severe toxemia of pneumonia frequently hides important symptoms from the attending physician. Fussell's paper is of real service in calling attention to one complication of pneumonia for which the physician must be constantly on his guard.

The Alleged Sanitary Menace of the Panama Canal.

A few years ago Sir Patrick Manson, lecturing on tropical diseases at the Cooper Medical College of California, voiced his fears that by means of the Panama Canal yellow fever might be conveyed to the teeming masses of tropical Asia, and other writers have followed in the footsteps of this great authority on tropical diseases. Events have, however, shown that his fears were groundless, and Juan Guiteras, writing in the Bulletin of the Cuban Department of Sanidad y Beneficencia for August, 1911, ridicules these fears for the seemingly very sufficient reason that yellow fever is wholly extinct even now in the Panama region. Furthermore, Guiteras suggests that the British acuteness of vision that sees the mote of yellow fever upon the Isthmus might, perhaps, be better employed in contemplating the beam that projects its shadow upon the map of India, in order that tropical Asia may cease to be a perennial pesthouse and stock for the distribution of cholera and plague throughout the world. The writer is of the opinion that the Indian authorities have not met the requirements of the situation with regard to grave problems of plague and cholera with all the energy

they demand. He contrasts the methods in vogue in this respect in the Philippines and those in India to the disadvantage of the British methods. He thinks there will be a greater danger to India and China from the propagation of yellow fever through equatorial Africa to the Indian Ocean than through the Panama Canal. The western coast of Africa may, indeed, become, in his opinion, the storehouse of yellow fever. Finally, considering the example set by the Americans on the Isthmus, and the lesson of Cuba, of Mexico, and of Rio Janeiro, the writer contends that the Panama Canal instead of being looked upon as a possible menace must be regarded as a guarantee against the spread of epidemic diseases by land and sea.

Progress in Skiagraphy.

One of the chief lines along which röntgenography is developing consists in the recognition of characteristic shapes assumed by the more indistinct types of shadow caused by special organic diseases. Designations of this sort are multiplying to such an extent as to suggest old and forgotten nomenclatures based on first hand observation before the introduction of diagnostic instruments of precision. Thus Grödel and Truepel in a recent address before the Aerztlicher Verein of Frankfurt (*Berliner klinische Wochenschrift,* October 30) enumerate various forms of "heart silhouette" as revealed by orthodiagraphy. There is the "spheroidal heart" of mitral insufficiency, the "standing ovoid" of mitral stenosis, and the "recumbent ovoid" of aortic valve disease. The pulmonary arch pouches out in persistent Botal's duct. Aortic aneurysms are readily recognized. Displacement of the heart from outside influence is easily apparent. The much deeper and more sharply defined shadows obtained by filling hollow and tubular organs with solutions of bismuth, silver, etc., show naturally an even greater variety and certain shadows are even characteristic of complicated conditions which could not be otherwise determined save by exploratory laparotomy, and perhaps not then. Thus a double perforating round ulcer of the stomach was actually made out by skiagraphy alone. Similar advances are reported in the skiagraphy of the urinary apparatus (pyelography).

Tuberculous Infection in Childhood.

That children are more susceptible to bovine tuberculosis than are adults is a conclusion that has been derived from a number of recent investigations into the type of bacillus in cases of human tuberculosis. This conclusion, however, has not remained unchallenged. In a careful examination of the bronchial and mesenteric glands of 400 children that had died from various causes, Rothe* found that, while 20 per cent. of the cases showed the presence of tuberculosis, in only one instance was the disease of bovine origin. Furthermore, it was shown that the portal of entry of tuberculosis in children in the vast majority of cases is the respiratory tract, just as in adults. The observations are therefore in agreement with the original contention made by the discoverer of the tubercle bacillus, namely, that the bovine organism is of little pathogenic significance so far as the human being is concerned. Nevertheless, the results of the investigations made by the British Tuberculosis Commission, and by Park in America, while they show the minor rôle of the bovine type of bacillus, at any rate indicate that this is responsible, particularly in children, for an appreciable percentage of tuberculous infections. In view of these discrepancies in the results of the German investigators on the one hand and the English and American workers on the other, the question of the importance of bovine infection for human beings cannot, as yet, be regarded as definitely settled.

*"Untersuchungen über tuberkulöse Infektion im Kindesalter. Veröffentlichungen den Robert Koch-Stiftung zur Bekämpfung der Tuberkulose. Heft. 2. Leipzig: Verlag von Georg Thieme, 1911.

News of the Week.

Homeopathic Practitioners of New York Urge Dr. Doty's Retention.—The Homeopathic Medical Society of the County of New York has added its testimony as to the value of the services of Dr. Alvah H. Doty as Health Officer of the Port of New York by passing resolutions expressing the confidence of its members in the efficiency of his administration of the office and in requesting Governor Dix to reappoint him as Health Officer of this Port.

Research Institutes and Universities.—In his annual report President Nicholas Murray Butler of Columbia University says it is a mistake to establish research institutions such as the Carnegie Institution of Washington and the Rockefeller Institute of New York separate from universities; they would do more effective work if they were connected with a university. Dr. Butler says the notion that research work cannot be successfully carried on together with teaching is a great mistake and points to the fact that during the past one hundred years nine out of every ten of the leading scientific investigators have been teachers and that some of the best and most original work was done by those overburdened with teaching.

Hospital Ships Needed for the Navy.—Surgeon-General Stokes has made the recommendation to the Navy Department that a properly equipped hospital ship be supplied for each of the Navy's fleets. He points out that no community of 14,000 persons ashore would be without a well-appointed hospital, and yet the 14,000 men and officers of the Atlantic fleet have only the inadequate facilities afforded by an old merchant steamer converted into a makeshift hospital. The department is asked to replace this old vessel by a properly equipped hospital boat.

Ban on Absinthe.—The Pure Food Board of the Department of Agriculture decided on December 14 that the importation of absinthe into the United States should be prohibited after January 1, 1912, under the Food and Drugs Act. The order awaits only the signature of the Secretary of Agriculture before becoming effective. This board also announces a series of new regulations aimed at the restriction of the importation of opium, morphine, and cocaine, which likewise awaits the signature of the Secretary of Agriculture. Every purchaser or receiver of drug imports will be required to fill out a declaration stating the amount and the proposed use of the drug.

New York's Birth Rate Increases.—The records of the Health Department show that there were 10,825 births in New York City during the month of November, an increase of 236 over November, 1910. There were only 5,620 deaths during the month, or a rate of 13.73 per 1,000 population.

This was lower than the average death rate for November since the formation of the Greater City in 1898. Child mortality decreased during this time from 37.05 to 28.97 deaths per 1,000 population, or 22 per cent.

Vaccination Against Typhoid in Torrington, Conn.—The State Board of Health in its Bulletin of December 15 gives the results of vaccination against typhoid fever resorted to during the recent epidemic in Torrington. About 400 persons were voluntarily vaccinated, and among these only one case developed. The disease developed after the second inoculation and ran a very mild and short course.

A Campaign Against the Common Towel.—At the meeting of the county health officers of the State of Connecticut in New Haven on December 7 it was decided to notify every hotelkeeper in the State before January 1 of the law passed by the last general assembly prohibiting the use of common towels in hotels and in other public places.

Antivivisectionists Begin New Campaign.—Some two hundred members of an organization, composed mostly of women and calling itself the Vivisection Investigation League, met on December 16 at the residence of Mrs. Stuyvesant Fish, where John Sherwin Crosby told them that they ought to insist on the passage of a bill that would establish a commission to see that vivisection was carried out under proper conditions. A benefit performance was recently given in one of the New York theaters to furnish funds for this campaign.

A Revolt Among the Eddyites.—The Christian Science Church of East Orange has declared its independencce of the mother church. The most generally interesting departure from the mother church is that medical treatment for children is advised and that members when called to treat certain cases of sickness will see that all the requirements of the State of New Jersey and the local Health Department will be complied with.

Exclude Opium from China.—A special despatch to the *Sun* from The Hague states that a resolution introduced by a Chinese delegate excluding all opium imports from China except such as were made under the Indo-Chinese agreement of May, 1911, was adopted by the Opium Congress on December 12.

Dr. John M. Baldy has been elected president and Dr. Nathan C. Schaeffer secretary of the new Pennsylvania Board of Medical Licensure.

Dr. Joseph S. Neff, who had been reappointed director of the Department of Health and Charities of the city of Philadelphia, has been presented with a gold chronometer watch by about one hundred prominent citizens as a testimonial of their appreciation of his official services.

Dr. Ralph W. Montelius of Mount Carmel has been appointed a member of the Board of Trustees of the new State Hospital of the Treverton, Shamokin, and Mount Carmel coal fields by Governor Tener.

Eleanor Colley has been admitted to fellowship in the Royal College of Surgeons of London. She is the first woman to be honored with that distinction.

Dr. John H. Huddleston, secretary of the New York Academy of Medicine, is recovering from a four weeks' illness with pneumonia.

Miss Catherine C. De Long, for many years superintendent of the Johns Hopkins Nurses' Home, has accepted the superintendency of the nurses' home at Bellevue Hospital, New York, while Mrs. T. Simpson, whose place Miss De Long will take, has been called to the Illinois Training School in Chicago.

Dr. Reynold Webb Wilcox has been elected president of the Society of Medical Jurisprudence.

Hospitals Object to Alcohol Fine.—Efforts are being made by hospital authorities in Baltimore, in common with hospital officials all over the country, to have the Treasury Department rescind the fines recently imposed for using alcohol and other drugs without paying internal revenue tax. The fines imposed on Baltimore hospitals amounted to more than $75,000, and the law, if imposed, will become a serious burden to the hospitals. It is said that, in the event of the Treasury Department refusing to have the fines rescinded, bills will introduced into Congress appropriating to each hospital an amount equivalent to the fine.

Lay Cornerstone for Cancer Hospital.—The ceremony of laying the cornerstone for a new St. Rose's Home for Cancer Incurables took place on December 16, Mgr. Joseph E. Mooney, representing Cardinal Farley, conducting the service. The new building is located at Jackson and Front streets; it will be five stories high, built of limestone and terra cotta brick with a steel frame, and will cost about $91,000. It will accommodate 100 patients and will be completed by June 1, 1912.

A New Hospital for Red Bank, N. J.—Mrs. Peter Fenelon Collier, the widow of the late publisher of *Collier's Weekly,* has given $60,000 for a new hospital to be built at Red Bank and to be named the Peter Fenelon Collier Memorial Hospital. The hospital will be non-sectarian and will have an ambulance service.

Lutherans to Build Hospital.—The St. Andrew's Hospital Association of Minneapolis has purchased property in that city for a site for a new hospital. The building planned will have accommodations for 100 patients and will cost about $100,000.

The New York Post-Graduate Medical School and Hospital announces that its new buildings and laboratory, which have just been completed, will be formally opened on the afternoon of January 11, 1912.

Many Red Cross Seals Sold.—The Committee on the Prevention of Tuberculosis announces that up to December 15, 700,000 Red Cross Christmas seals had been sold in New York City. These sales do not include those made by agents throughout the city. The sales of the seals from department stores and sub-postoffice stations are bringing in more than $150 daily.

The East New York Medical Society, an organization recently formed in the East New York section of Brooklyn, has elected the following officers: *Recording Secretary,* Dr. Joseph B. Kanter; *Corresponding Secretary,* Dr. H. Kalperin; *Treasurer,* Dr. G. Krimsky. Instead of a president, a temporary chairman is elected at each meeting. Meetings are held twice monthly, on the second and fourth Wednesday, the first being a business and the second a scientific session.

The Southern California Medical Association, which met in Los Angeles on December 7, elected the following officers: *President,* Dr. Charles C. Browning of Los Angeles; *Vice-President,* Dr. F. A. Mead of San Diego; *Secretary,* Dr. J. M. Clark of Santa Ana.

The Clinical Society of the New York Post-

Graduate Medical School and Hospital at its meeting on December 15 elected the following officers: *President,* Dr. Henry Dawson Furniss; *Vice-President,* Dr. W. J. MacNeal; *Secretary,* Dr. Ralph Tousey; *Treasurer,* Dr. Henry G. Bugbee.

Obituary Notes.—Dr. Conway B. Ackley of Denver, Col., a graduate of the Northwestern University Medical School, Chicago, died on December 6 at the age of 33.

Dr. Charles J. Burke, Assistant Registrar of Vital Statistics of the New York Health Department, died December 17 of pneumonia at his home in Mount Vernon after an illness of five days. He is survived by a widow and two children and two brothers, the Rev. Edward Burke, a professor at Holy Cross College, and Dr. William Burke of Middletown, N. Y.

Dr. Hugh Blake Williams died at his home in Chicago on December 4 at the age of 52 years. He was graduated from Tulane University, New Orleans, in 1884, and at the time of his death was a member of the faculty of Loyola University.

Dr. John T. H. Slayter, formerly a military surgeon in the Philippines, and later a resident of Helena, Mont., died at his home in Watertown, Mass., on December 1. He was graduated from the College of Physicians and Surgeons, New York.

Dr. J. Q. Wilbur died at the home of his daughter on December 4 at the age of 80 years. He was a surgeon on the Confederate side during the Civil War and had practised his profession for more than fifty years.

Dr. G. A. Ferdinand Reinhard died at his home in Baltimore on December 2 at the age of 80 years. He was born in Germany and graduated from the University of Marburg. He came to this country in 1865.

Dr. David Richard Fly of Amarillo, Tex., died at Forth Worth on November 29. He was born in 1865, graduated from the Kentucky School of Medicine, Louisville, in 1894, and at the time of his death was president of the State Medical Association.

Dr. Erion Erle Maddox, a graduate of Hahnemann Medical College, Chicago, in 1897, died at his home in Rockville, Ind., on December 1, after an illness of six months. He was 37 years of age.

Dr. Marion H. Barker of Forest Grove, Ore., died on November 29 at the age of 67.

Dr. Max V. Vander Horck died suddenly at his home in Minneapolis on December 5. He was born in 1862 and graduated from Jefferson Medical College, Philadelphia, in 1885. Since 1899 he has occupied the chair of genito-urinary diseases in the University of Minnesota.

Dr. George Henry McFarland of New York Ctiy died in Denver, where he went for his health some eighteen months ago, on December 4, at the age of 35 years. He was graduated from Princeton University and from the College of Physicians and Surgeons of Columbia University in 1902.

Dr. James W. Hannum died at his home in Ludlow, Mass., after a long illness on December 9. He was born in Williamsburg in 1851 and was graduated from the College of Physicians and Surgeons of Columbia University, New York, in 1877.

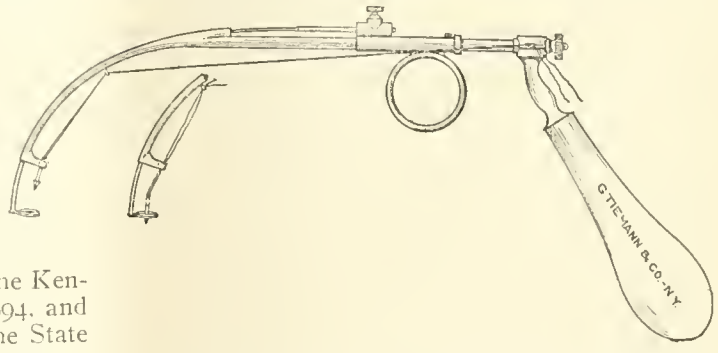
Dr. A. L. Harris, a retired physician of Birmingham, Ala., died at his home December 7, aged 74 years.

Correspondence.

THE EPIGLOTTIC SUTURE.

To the Editor of the Medical Record:

Sir:—In the Medical Record of December 9 there appears under the above title a description, with drawing, of an instrument by Dr. Cyril Horsford, shown at the International Laryngo-Rhinological Congress at Berlin, 1911. It is intended for passing a suture through the epiglottis by the aid of a needle threaded with a long piece of silk, thus holding the epiglottis against the root of the tongue. Dr. Horsford conceived his first idea July, 1906, and considers his latest instrument—called by him "The Epiglottis Suture Forceps No. 2"—the most efficient one. In his remarks he mentions, besides several authors trying to accomplish the same object, also the name of the writer, allowing the inference that he was acquainted with his work in this line. As the original article was not available, his opinion as to the instrument of the writer cannot be ascertained. The latter began to develop devices for this purpose as early as 1898, as shown by the records in the books of Tiemann & Co., the instrument makers, and had the instrument shown in the cut made by the same firm. It was demonstrated later at a meeting of the Laryngological Section of the New York Academy of Medicine March 27, 1907, and published in the *Laryngoscope* May, 1907.



It is not necessary to enter here at length into the action of the instrument, except to state that when the epiglottis has been pierced by the needle the latter is held fast by two spring-plates, thus enabling the whole instrument to be withdrawn, the epiglottis hanging on the thread.

It was called the "Self-Acting Epiglottis Lifter," and was the first instrument which allowed the needle, after having pierced the epiglottis, to be withdrawn without any other manipulation.

Comparing the two instruments, their similarity is evident, the principle being the same, only the size of the needle and the curve being different. But the greater curve of the writer's instrument appears to him more suitable, as the gentle curve of Horsford's instrument may make with a thick tongue, with a deeper situation of the epiglottis, etc., the introduction more difficult. Further deductions the writer leaves to the reader.

J. W. Gleitsmann, M.D.

616 Madison Avenue, New York.

Daily Cycle of Phosphoric Acid Elimination.—Sarvonat and Genty found that this elimination is greatest at night, and chiefly during its second half. This is true both of the healthy and of the tuberculous.—*Province Médicale.*

OUR LONDON LETTER.

(From Our Regular Correspondent.)

BUTLIN'S HUNTERIAN LECTURES ON CANCER—MEDICAL SOCIETY'S ADJOURNED DEBATE.

London, December 1, 1911.

Sir Henry Butlin devoted two Hunterian lectures on the 13th and 18th ult. at the Royal College of Surgeons to the parasite of cancer—*Unicellula cancri*. As long ago as 1905 he put forward the proposition that the cancer cell is an independent organism, like many a protozoon, living a life proper to itself, as a parasite "doing nothing to repay its host for the sustenance of which it robs him." Powell, White, and Hanser had previously spoken of the cancer cell as behaving like a parasite by taking on Adami's "habit of growth." But Sir Henry goes farther and regards it as a new organism, "a new creation of animal being—not a mere changed cell." This view he maintained in his Bradshaw lecture (1905) and now from further study of the material accumulated since he maintains it not only for carcinoma, but for every variety of malignant disease. He makes no pretense of possessing all the kinds of knowledge involved, is content to be a clinical pathologist who has spent years in studying cancer, and depends for his statements about the life history of the protozoa on the works of Calkins and Doflein. He endeavors, firstly, to show that there is no essential difference between cancer cells and certain other parasites in their relation to the host, and, secondly, that all the phenomena of cancer can be explained on this theory. He does not say cancer cells must be included in the protozoa but that they most resemble them in relation to the body of the host and perhaps in their mutual relations. He points out that some protozoa only live as parasites, others are never parasitic, and others can exist in either way. But, further, many are limited as to their hosts, many as to the particular organ or tissue of their special hosts. Some take an active part in their migration, others are passively carried by the blood and lymph. Many die when their host dies, many are killed by being invaded by bacteria—an important fact in reference to cancer cells. Many parasites produce toxins in regard to their hosts, *e.g.* the malaria parasite. The non-toxic may, however, injure and destroy cells or tissues which they invade or produce tumors or other effects dangerous or fatal to their hosts. It seems too that some parasites may exist in their hosts in a torpid condition and then after a long time become active. A patient who has had malaria and afterwards lived in a non-malarial region may be suddenly attacked afresh as if the person has become immune but for some reason has lost that immunity. The lecturer stated two other characters: if in a suitable host it does not reach a suitable part of the body in a reasonable time it dies; secondly, it breeds true. He then proceeded with a comparison between cancer cells and the parasitic protozoa, enumerating many resemblances. Clinically one of the most important is that they are never transformed into the tissues of the host, nor do they transform the body cells into cancer cells. Nor do carcinoma cells produce sarcoma. It is invariably the same variety which is reproduced. The points in which the cancer cell differs from parasitic protozoa were quoted by Sir Henry from a letter to him by Professor Calkins of Columbia University, New York, as (1) The cancer cell, so far as we know, undergoes no processes analogous to fertilization; (2) cannot live apart from the organism in which it grows; cannot be cultivated on artificial media as we cultivate amebæ and flagelates. As to these two points Sir Henry observes that already two workers in the Rockefeller Institute claim to have cultivated the cells and if in future no process analogous to fertilization be discovered the import of that process will have to be reconsidered.

Passing to the phenomena of cancer the first point was the tumor; it might be a trivial thickening at first but if examined microscopically would be seen to be composed of cancer cells massed together without law or order or, on the other hand, woven with wondrous skill like a natural tissue. There was also provision for maintenance, vessels, etc., forming a sort of scaffold or frame for the cells, the essential elements on which the tumor depends, for if they waste or die they are devoured by phagocytes. Perhaps this happens more often than is supposed. If they thrive they multiply and the tumor extends. In an organ like the breast it may become a large lump, in a limb, round the bone, enormous. The advance is seen in the destruction of the tissues, all of which may be replaced by cancer cells and their framework, but not all at the same pace or in the same manner. Sometimes the tumor atrophies from death of cells in the center but that is not cure as the margin may grow. All these changes are explicable if the cancer cell is an independent organism pursuing the same objects as parasitic protozoa—the maintenance of itself and reproduction. Another phenomenon, metastasis, might be due to the cells penetrating the interstices of the tissues or being carried by the blood or lymph. Metastasis is migration of the cells, precisely as with the protozoa the cells seek the places where they can live and multiply.

Six years ago the lecturer came to the conclusion, reluctantly, that the evidence in favor of the formation within the body was stronger than that of entrance from the outside. He said "reluctantly" as that implied logically a new species of living creatures being created in a way never previously imagined. But during those six years the evidence had grown stronger. There were the resemblances of the cancer cells to those of the tissues in which they start; of the secretions; of the degenerations; of the groupings; of the mode of reproduction of the normal and abnormal cells. These points may be regarded as traits of atavism but they explain some of the phenomena. Biologists and research workers are bent on finding why the cancer cell behaves so differently from the cells it is derived from. There is one and only one explanation, declared the lecturer. It has been endowed with the gift of life and become one independent creature. To borrow the figurative language of Scripture, the Creator has breathed into it the breath of life. Implant a normal cell—you cannot make it live. Implant a cancer cell—you cannot kill it. If it be a new creature in what class is it? It is nearest protozoa, but biologists will have none of it. So Sir Henry provides this, calling it *Unicella cancri*, to which as required qualifying terms may be added such as *squamosa*, *rotunda*, and so on.

The adjourned debate at the Medical Society of London was brought to a conclusion on November 20, all the speakers joining in full appreciation of Dr. Mott's opening paper. Dr. R. Russell agreed that in general paralysis mercurial treatment failed but in early tabes it should always be given in in-

unction or injection. Failure of the pupil to react to light proved organic disease; not so mere inequality of the pupils, which was not uncommon in neurasthenia. In cerebral syphilis headache was usually more severe than in neurasthenia though not invariably, for he had known a case of the latter in which trephining had been proposed. The cerebrospinal fluid was negative and the patient made a good recovery. He endorsed all that had been said of the Wassermann test. Ankle clonus and extensor plantar reflex were not of the value some have attributed to them in the diagnosis of brain cases from general paralysis.

Dr. Buzzard agreed that the pathological process underlying tabes was not a gross structural one like the inflammatory lesions of syphilis, but regarded it as an active intoxication rather than neuronic decay. The so-called parasyphilitic diseases were in reality the only syphilitic diseases of the nervous system, for cerebrospinal cases were those of its supporting and nutrient tissues. He believed that mercury rarely, if ever, did harm to tabetics; it was the most potent agent for arresting the progress of their disease. He was not so positive about general paralysis but he had thought it had benefited many cases, if only temporarily. The pains of tabes were often called rheumatic but the lightning pains were really unlike any others and so characteristic.

Mr. Fleming dealt fully with the diagnosis in relation to the clinical laboratory. He summed up the uses of the Wassermann reaction in nervous diseases as (1) to decide if the patient had syphilis (by the serum); (2) by the spinal fluid to detect parasyphilis (especially general paralysis); (3) to reassure a patient who had been cured.

Major French sent a written communication in which he stated that brain and spinal cases were rare in the army, which was due to the judicious use of mercury in primary infection and also to the fact that soldiers left the army as a rule under forty years of age. He had been told by Dr. Levy-Bing in Paris of five hundred injections of salvarsan without aborting the disease in any though the Wassermann often became negative but returned positive again within two months. The prevailing opinion was that mercury should be given for three years.

Mr. H. W. Bayly reported results of Wassermann tests at Queen Square hospital. With serum 70 per cent. gave a positive in tabes and 88 per cent. in general paralysis.

Dr. Wilfred Harris had hoped to have heard something about a special neurotoxin for tabes and general paralysis. There were instances of several persons infected from a single source. In one seven were infected from one blow-pipe and five of them developed tabes and general paralysis.

Lt.-Col. Scanlan, R.A.M.C., disagreed with the statements that syphilis was practically the cause of tabes. It was only one cause.

Dr. H. Corner thought something beyond syphilis was needed to produce general paralysis, of which the progressive character was very different from other syphilitic lesions.

Dr. Mott in reply answered several questions and thanked the speakers for their reception of his paper.

Dr. W. H. Hamer, whose work in the Public Health Department of the County Council has been conspicuous for many years, is to succeed Sir Shirley Murphy as Medical Officer of Health and School Medical Officer for the County of London.

A VISIT TO THE INTERNATIONALE HYGIENE AUSSTELLUNG, DRESDEN, 1911.

(From an Occasional Correspondent.)

The International Exhibition of Hygiene which was held at Dresden this year must be recognized by the future historian of the healing art as one of the most prominent and most significant landmarks of the progress of our knowledge of disease, and of the ways and means suitable to the prevention and cure of its manifold types and individual modifications. Also, as a convincing monumental proof of the parallel advances of each of the various auxiliary and ancillary sciences along their special lines of research and conquest, aided, perhaps, by the activity provided by the stimulus of national rivalry (even by that of racial prejudice); and, of recent years, made to converge so as to secure the meeting in a single cosmopolitan focus of all the available radiations of the common enlightenment of civilization. The central position of the beautiful and interesting Saxon metropolis was well suited to the most complete exhibition of the ways and means collectively devised and finally selected by struggling humanity in its attempts at self-preservation in presence of the germs of disease. Associations, racial and geographical, appeal strongly to the whole Anglo-American public on both sides of the Atlantic, and, indeed, all over the world. The focal settlement which represented the original germinal layer of the capital of Saxondom also furnished that of the body of the present Anglo-Saxon race. The group of Wendish "spores" which emerged from their forest homes to make a broad clearance for themselves on the right bank of the Elbe furnished the successful "culture colony" which was known in mediæval times as *Drjezdjenje* (home of the woodmen), a term which was filed down to our modern Dresden. The future beautiful and artistic metropolis grew from the absorption of the region, in the year 922, into the *Markgrafshaft*, which was founded under King Henry I. The wave of Germanic development soon overwhelmed the Wendish Altdresden, and the markgräfliche burg blossomed and bore its principal fruit on the left bank of the Elbe; but the union of the two sections into a single stadt was not completed till 1550. When the division of the Saxon territory between the brothers, Kurfürst Ernst and Herzog Albrecht, was carried out in 1485 Dresden fell to the latter and has been retained ever since as the residence of the representative of the line. How thoroughly and how patriotically both prince and citizen have discharged their duties, to themselves and to one another, is well displayed to the perceiving eye, even by a cursory glance at the beautiful, artistic, and hygienic city of which the picturesque position is so exquisitely emphasized by the graceful architecture of the splendid series of bridges which span the intersecting stream. It is more than doubtful whether any European city of the present day can be said to justify the eleven hundred years of its growth and development more satisfactorily than that which was so happily selected for the site of the greatest exhibition that the world has yet seen of the ways and means that modern art and science have devised for the preservation of health and the prevention of disease.

It seemed not a little remarkable to the casual scientific visitor to find that a display on which so much thought and labor, as well as time and space, had been skilfully as well as ungrudgingly ex-

pended was so slenderly advertised as to have attracted very little of the general public attention. The explanation offered by exhibitors was they did not appeal to the general public, but to medical men who must necessarily know of the existence of the exhibition. Still there can be little doubt that more advertising would have attracted a vastly greater number of visitors, and made the intelligent local business man and the touring foreigner far more appreciative of, as well as intimate with, the powers and objects of the embarrassing wealth of scientific mattrial displayed in the vast *Ausstellung*.

The site selected for the exhibition was worthy of this architecturally graceful capital. The entrance itself displayed architectural taste of distinctly Hellenistic type—a Propylæum-like series of gracefully pillared openings. After passing the turnstile the eye of the visitor was greeted by the display of guide books and catalogues that claimed his attention, and which, it must be added, were characterized by a thoroughness in detail of execution and in wealth of illustration which were entirely in keeping with the whole organization of the exhibition which they represented. The present writer was delighted to find that the *Historische Abteilung* (located in the *Steinpalast*) first claimed his attention. For he had long been an ardent champion of the view that what really sound and reliable knowledge we do possess of the healing art in the broadest and firmest sense is that derived from historic sources and empirical methods. The ways and means of clinical research, of physiological and pathological physics, do not yield themselves to the methods and rules of mathematical demonstration. And the best, indeed the only reliable, remedies even now utilizable at the bedside are those of which the efficacy was originally discovered by early empiricism. (Less than a decade will, pretty surely, decide whether "606" is destined to displace Hg permanently.) Also, the utter and wilful neglect to preserve a continuous traditional record of clinical experience and therapeutic efficacy must be held largely responsible for the unsatisfactory character of the progress of medicine, and surgery, and hygiene, and sanitation. The thinking observer was there, indeed, furnished with a vast fund of material for the repair of the spaces eroded by the tooth of time in the defences of a treacherous memory, and for supplying with the best existing furniture the untenanted spaces which occupy far too large a proportion of the byways of even the most cultured professional organ of mind. A series of forty-seven rooms displayed the recorded, as well as existing, methods and means of sanitation; from the prehistoric evidences of fossil remains and geological preservation down to the most complicated cosmetics and drainage, of dietetics and appliances for preservation from accident and safeguarding of life and limb, bathing, dress, housing, lighting, heating, diet, exercise, bedding, nursing, traveling, care of the sick, of the infirm, of children, the hygiene of the camp, and that of the prison, down through all the ages; all those were there represented by object lessons convincingly displayed. A forest of landmarks of the various stages of human research, and gradual or spasmodic enlightenment; monuments of epoch-making advances and discoveries; saddening evidences of devolution, of catastrophic oblivion, of unaccountable alteration of custom and of caprice in matters concerning human comfort and attempted conquest of Nature; of the vast influences of geographical, geological, and climatic conditions and environment on the development of the human body, mind, habits, tastes, and general disposition, temperament, and character all the way down from prehistoric antiquity to the closing year of the first decade of the twentieth century. Prehistoric, barbarian, Babylonian, Egyptian, Jewish, Mexican, and Peruvian hygienic codes of the most antique respective dates were shown in series with the Anglo-American, French, German, Italian, Spanish, Swiss, Danish, Scandinavin, Russian, Turkish, Persian, Arab, Hindu, Burmese, Chinese, Japanese, Korean, and Tibetian of the present day, and with those of less important nationalities and communities. And the whole mass of graduated, standardized and welded material was ground down to the finest "modern" edge at the terminal stage of the most recent scientific, "modern" hygiene, with its inoculation, and immunization, and asepsis, and statistics!

Then the contrasted methods of current civilizations were displayed in admirable serial detail in the *Ethnologische Unterabteilung*. The present prevailing sanitary conditions of the homes and public edifices of the Celestial Empire, which has so recently commenced to brush from its eyes the cobwebs of its lethargy of four thousand years, can be studied side by side with those of the Land of the Rising Sun, and the Land of the Morning Calm. The sanitation of dignified and despotic Islam, which will inevitably be made more familiar to the eyes and ears of Western communities in the very near future, is illustrated in an admirable series of plans and models, with, as in the case of every other department, copious and luminous descriptive literature. The picturesque, often very startling, contrasts of the racial, climatic, and temperamental conditions and characteristics of East and West, also of tropical, temperate, and polar, are here displayed so vividly as to impress the minds, and elicit the curiosity, of the most stolid and careless. The hunting methods of the natives of Central Africa are extensively illustrated, as are the piscatorial practices of the Eskimos and Icelanders in a neighboring compartment. The dress, weapons, and domestic sanitation of Turk and Hottentot, of Arab and Samoyed, of Sikh and Cingales, of Lama and Brahman, of the prudent and cultured (Zoroastrian) Parsee, and of the dreamy and self-annihilating Buddhist, of the Kamschatdale and the Patagonian, the Maori and the Filipino, and all the others, of every race and locality, have been collected under the roof of a single enclosure, and displayed to the eye of the inquiring visitor with an instructive skill, as well as luxury of illustrative wealth, which has never before been approached with the same success. It is no disparagement to the attainments of the cultured citizen of the great American Commonwealth to say that it is only members of the front rank of specialists who would not derive new knowledge and intellectual expansion from an examination of Raum III, which accounted for *Die Kulturwelt Altamerikas*, with its wealth of specimens and models demonstrative of the prehistoric hygiene of the American mound builders and cliff dwellers; as well as of the splendidly constructive civilizations of the gorgeous capital of Montezuma, and the more than modern agrarian socialism of Peru in the golden age of the monarchy of the Incas. How few people of the present day have any idea of the remote existence of the splendid *Kulturwelt* of the Antilles, of which the main traces and records have been almost

literally wiped off the face of the earth. And those who had been induced by the reverberations of the reports of progress of the Panama Canal to examine the map of Central America were further enlightened here by the evidences of the remarkable culture and civilization which characterized the ruined cities of Yucatan in the period of their glowing prosperity. And the Eden-like Mexico of the date of the advent of the rathless Spaniard, and the primitive hygiene and sanitation of the unsophisticated communities of the Polar Circle.

In the present state of medical knowledge and medical research it is inevitable that Saal 5, which dealt with *Infectionskrankheiten* should form one of the most attractive centers of interest, to both professional and lay visitors. And the demonstrative information provided in the compartments which accounted for *Mikrobiologie und Parasitolgie* and *Immunität und Schutzimpfung*, among others, surely merited the highest praise that a critical inquirer could well give, and were in themselves well worthy of a scientific pilgrimage from any part of the civilized world. Very appropriately, too, the next section was devoted to the allied *armamentarium* of the sanitary specialist, *Disinfektion;* and the collection of apparatus and appliances presented full opportunities for a liberal education in this department. Saal 6 introduced the visitor to the most up-to-date acquaintanceship with *Tropenhygiene;* the etiology, symptomatology, and geographical distribution of the tropical diseases of which recent literature has made us read and hear so much, and of the hygienic prevention and possible extermination of the same. Saal 7 exhibited treasures of *Statistik*. And I cannot leave this subject without specially calling attention to the more than Teutonic thoroughness with which the statistics of every department had been prepared. This could be seen at its acme of demonstrative efficacy in the volume, *Die Deutsche Arbeiter Versicherung, Blatt,* 1 of which displayed the genealogical tree, with its three great branching systems: *Kranken-Versicherung, Unfall-Versicherung*, and *Invaliden-Versicherung*. Indeed, one of the most impressive lessons necessarily conveyed to every thoughful visitor of the unique exhibition was the completeness of every imaginable detail of scientific precaution for the safeguarding of the health and life and limb of the working man of every variety of occupation, throughout every section of the German Empire. The most demonstrative, and wholly convincing, documentary evidence of the parental care with which every known scientific principle and every known mechanical invention is now continually utilized in the personal interest of the German artisan is, however, to be found in the truly monumental work: *Unfallverhütung und Betriebssicherheit: Denkshrift des Verbandes der Deutschen Berufsgenossenschaften aus Anlass des 25 jährigen Bestehens der gewerblicher Arbeitversicherung (Unfallverhütungstechnik. Dr. C. Schlesinger . . . eingeleitet durch eine Abhandlung Berufsgenossenschaftliche Unfallverhütung in ihrer Entwicklung von* 1885 *bis* 1910, *von Dr. K. Hartmann)*. The casual reader who scrutinizes the ponderous title of an imperial octavo of XX + 1231 pages, glistening throughout with illustrations and weighing nearly nine pounds avoirdupois, will be led to suppose that the text must be of unprecedented solidity if the expectations thus aroused by physical appearances are to be realized. And we can assure him that the scientific and logical qualities of the contents of this colossal landmark of the progress of technical means and methods, and technical literary record of the same, will successfully stand the severest test that the critical expert of the present day can fairly apply. And a perusal of its contents will carry conviction of the fact that the authorities of the great Teutonic Empire have anticipated every personal care of the safety of the working man that could well be formulated by any, even moderately sane, demagogue. That twenty-five years' record is surely a unique one in the annals of human progress and does honor not only to Germany, but to the collective human race. It is, perhaps, the most powerful document that the optimist of the present day can attach to his brief.

But the literature of the exhibition was quite as distinctive and as finished a feature as any other of its wonderful series of exhibits. Another conspicuous example of the truly Teutonic thoroughness with which its volumes and booklets were prepared was one drawn up for the instruction of inquirers interested in the comparative hygiene of the races of man. This wonderful octavo of 282 pages gives, in a series of chapters, an account of reproduction, variation, selection, mutation, inheritance of acquired characteristics, laws of heredity, Mendelism, degeneration, race hygiene, and Neomalthusianism, of which each is a model of the most concentrated and up-to-date presentation of the most advanced views and results of research in the respective departments. The whole is copiously and most instructively illustrated, and the perusal made the present writer somewhat bitterly conscious how manifold the brain wrackings and heart sinkings such a volume would have saved him if available in the bygone years of his own enthusiastic pursuit of knowledge under difficulties. The Schema, on page 49, for instance, which illustrates *Quanitative Variabilität nach Bastardierung bei Selbstbefruchtung*, shows at a single glance more of the results of the mysterious laws of Mendelism than can well be gathered from weeks of reading of some of the indescribable literature with which the subject has been so profusely decorated.

The department of *Bader und Kurorte, Mineralwasser*, which occupies Halle 13, was one of the most interesting, perhaps, to the average "practical" modern mind. For everything known regarding the meteorology, climatology, geology, and chemistry, as well as geography, of all the famous mineral springs and health resorts of the Continent were there concentrated. The hygiene of air and light are there illustrated in all their varied aspects.

What science and altruistic thought and consequent endeavor can effect in helping those who are necessarily unable to help themselves was well shown in the department which deals with hygiene of infancy and childhood, as it was in the case of the average artizan. And the possibilities of the utilization of applied science in the care of the young and the menial, so wretchedly neglected in the golden eras of the "good old days," are paralleled by those so fully displayed in Halle 54 of the *Ausstellung*, of which the exhibits illustrated the problems of *Ansiedlung und Wohnung*, that take thought for all the conditions of municipal and domestic sanitation, of town planning, and the hygiene of the city and of the private residence: of their geological and meteorological adaptations; their lighting and heating, and collective and indi-

vidual breathing spaces, as well as the strength of materials employed; combination of utility and esthetics in architecture, and quantity and purity of water supply.

Very appropriately was the display of the essentials of the hygiene of the healthy home followed by the deterrent demonstration of the ravages of alcoholism, which was exhaustively illustrated by models, photographs, engravings, pathological specimens (macroscopic and microscopic), substantial volumes, and scattered leaflets. *Rassenhygiene* came next in order, and constituted for the scientific physician and philosophic inquirer one of the most interesting sections of the whole exhibition.

Halle 56 exhibited the mysteries of nutrition, illustrating exhaustively the constituents of human aliment in all the climes and centuries; the basic principles of choice, devices for obtaining, and stratagems, scientific and primitive, for preserving; the scientific basis of choice: the methods of nutritional adaptation and control devised by experimental, traditional, and physiological cookery, and the aids to digestion, absorption, and assimilation which have been devised and transmitted to posterity by the students of this science. Even the votaries of the shot gun and the fishing rod were charmed to find their specialty so understandingly dealt with in the *Sportabteilung* of this wondrous revelation of the needs and resources of gastronomy.

But these could not be overlooked in a display which takes corresponding thought for the possibilities of odontology and gynecology; of muscular training, of railway and ocean travel; of the special aspects and necessities of military, marine, and colonial hygiene; of the local requirements of the tropical and arctic zones; of the sanitary and hygienic demands of the prison as well as those of the playground, of the theater, and even of the military parade.

The most important section of the great exhibition, from the viewpoint of the "man in the street," was the *Populäre Abteilung* which was included in Halle 18; for there the cream of the scientific hygiene of the period, flavored with the sedimentary precipitation of the preceding ages, was to be found skimmed, pasteurized, and predigested for the intellectual nutrition of every intelligent visitor. Another impressive item of evidence of the earnest and philanthropic zeal with which the aims and methods of the German scientist are being made to anticipate those of the Socialist.

From this bewildering treasury of the temple of the Goddess of Public Health, the writer of this article at last tore himself, after a final visit to the department of *Geschlechtskrankheiten* (Saal 9 of the *Steinpalast*), in which every stage of every type and aspect of venereal disease was to be found illustrated by flesh-tinted wax models and gypsum casts, and a library, inclusive of every notable volume dealing with the subject that has appeared since the opening of the present century, with endless addenda of picture and pamphlet, all of which were continuously scrutinized by visitors of both sexes, of most ages, and of all civilized countries. Surely we are traveling fast in this age of the marconigram and the aeroplane! And with this parting reflection, I reluctantly leave the consideration of this demonstrative record of the most effective conquests of humanity at its philanthropic best.

Massachusetts Medical Society.—A. T. Cabot reviews the activities undertaken by this society in the public service during the one hundred and thirty years since its foundation.

Operative Treatment of Fractures.—F. J. Cotton presents the following summary of the recent fractures which require operative treatment: (1) Operable as a routine: compound fractures, fractures complicated with vessel lesions, fractures complicated with nerve lesions, patella fractures, fracture luxations, especially at the shoulder, acromioclavicular luxations. (2) Usually operable after trial of milder methods: carpal injuries, fractures of the femoral shaft. (3) Often operable: humerus fractures, leg fractures. (4) Operable on occasion: all fractures in fit patients that promise a bad result as they lie, even though they have had good care, provided that one can show good reasons for expecting a better result from operation.

Management of the Heart.—E. G. Cutler states that in pneumonia he does not favor the use of alcohol. In this disease morphine in small doses is a true heart tonic. Other drugs of value for this purpose are small doses of atropine and strychnine in alternation, and digitalis. In typhoid fever alcohol may be of service toward the end of the fastigium. In acute bronchitis in very young children and in the aged the heart is often better supported by spirits of nitrous ether and ammonia than by digitalis. In mitral insufficiency loss of compensation calls for tincture of digitalis in doses of twenty drops three times daily until the symptoms have disappeared, which will usually be in about three days. In aortic insufficiency, when dilatation gets to be in excess of hypertrophy, digitalis is to be used in doses of five drops three times a day, increasing the dose one drop daily until the proper results are attained, or until twenty drops three times a day are reached. An intermittent pulse in this condition contraindicates digitalis. The pulmonary symptoms of mitral stenosis are best met by the use of strophanthus and caffeine.

Renal and Pulmonary Tuberculosis.—J. H. Cunningham concludes from his experiments that it is not common, at least, for the tubercle bacillus to be eliminated through the kidney without affecting the organ in patients suffering from pulmonary tuberculosis. It does seem, however, that it is not the common thing for the bacillus to be eliminated in the urine in the usual form of phthisis. It may be that the bacillus is eliminated through the kidney in the miliary form of the disease in some instances, as there were 66 cases of miliary tuberculosis, while only 46 showed miliary tuberculosis of the kidney. Further evidence in favor of the passage of the tubercle bacillus through the kidney in the miliary form of the disease is found in five cases in which there was tuberculosis of the liver and spleen without evidence of the disease in the kidney.

Inguinal Bubo.—W. P. Coues from a study of the records of the past two years at the Boston Dispensary concludes that the cases in which the glands have been dissected out have not done as well as the cases in which the abscess was opened and drained, and the glands were left for future defense of the individual.

Nitrous-Oxide-Oxygen Anesthesia.—H. W. Kearney states that the backwardness of the profession in adopting this anesthetic may be accounted for to some extent by its inconvenience and expense as compared with ether and chloroform, as well as by the unfamiliarity with its action and advantages. Another reason is the prejudice which exists among physicians, in the minds of many of whom there arises at the mere mention of nitrous oxide a mental picture of the unpleasant appearance of the dentist's patient who has taken pure gas. Furthermore, there is misapprehension as to the cause and significance of nitrous oxide cyanosis. It is not appreciated that this symptom is due simply to lack of oxygen in the blood and that it is transient, not dangerous, and rapidly disappears on addition of oxygen, which is at instant command should emergencies arise. There is no specific poison to depress the circulatory center, which is a factor in the use of the other anesthetics which produce a cyanosis not due to respiratory obstruction and which really are dangerous.

Lateral Thoracic Glands.—M. Manges states that the presence of enlarged lateral thoracic glands, while by no means frequent, may at times be of value in giving early warning of the possibility of tuberculous infection of the lung. They may also be of value in corroborating the possibility of malignant disease of the lung, pleura, the posterior mediastinum, breast, or other more distant organs. As the mere presence of the glands does not necessarily denote malignant or tuberculous disease, but may only be a hyperplasia, excision and microscopical examination are the only means of positive proof of their carcinomatous or tuberculous nature. Their presence, in women, especially, should always require a careful search for suppuration in the adjacent or remote tissues, lest an erroneous diagnosis of carcinoma of the breast be made.

Reduction of Cancer Mortality.—J. M. Wainwright notes the following axioms: (1) Cancer in the first stage is always a purely local disease and permanently curable by complete removal. (2) Cancer nearly always indicates its presence while it is in this first local curable stage. (3) In about four-fifths of the cases cancer begins in regions which are accessible to surgery. (4) Most of the cancer deaths are due to delay.

Cancer Statistics.—I. S. Wile presents figures which show that cancer is increasing throughout the world and in all decades of life. The causes of this increase are still obscure.

Training of Nursery Maids.—C. G. Kerley describes the system of training nursery maids which was first undertaken in the United States in 1889 by the Babies' Hospital of New York. At the present time this system is conducted in over twenty different institutions in this country.

Rabies.—L. D. Frescoln reports a series of nine cases of this disease and reviews the present-day knowledge as to its nature and treatment.

Nomenclature of Poliomyelitis.—B. M. Randolph notes that the names under which poliomyelitis has been known are open to objection, because of their inaccuracy, incompleteness, or cumbrousness. He suggests the term acute infectious paralysis as best meeting the needs of the situation.

Tincture of Iodine in the Local Treatment of Infections.—E. M. Sill reports good results from the use of tincture of iodine applied locally in the treatment of various infections of the throat and nose in children.

Persistent Occipitoposterior Position.—S. Robbinovitz describes Jewett's method of treating a case of persistent occipitoposterior position.

Pruritus Ani: the Probable Cause and an Outline of Treatment. A Preliminary Report Based on Results of Original Research. D. H. Murray.

Surgery of Female Pelvic Organs.—By H. P. Newman. (See MEDICAL RECORD, July 8, 1911, page 104.)

Uterovaginal Prolapse.—By G. B. Somers. (See MEDICAL RECORD, July 8, 1911, page 104.)

Tuberculin in the Diagnosis and Treatment of Conjunctivitis.—R. J. Tivnen states that the tuberculous nature of conjunctivitis eczematosa is established and this opinion is supported by the results obtained in the cases subjected to tuberculin, both diagnostically and therapeutically, and by the majority of the other essential clinical findings. The cutaneous diagnostic tuberculin test is a dependable method for the recognition of tuberculosis, particularly in children. Tuberculin as a therapeutic agent in the treatment of conjunctivitis eczematosa is an agent of distinct and special value and should be employed faithfully and judiciously in this class of cases.

Cancer of the Uterus.—By A. E. Benjamin. (See MEDICAL RECORD, July 1, 1911, page 50.)

American Mineral Springs.—H. G. Klotz regrets the neglect which American medicinal mineral springs have received, and attributes this largely to the commercializing and monopolizing methods which have so far existed. Physicians recommend patients only half-heartedly to American resorts. To do away with this neglect it will be necessary to establish the American springs on the standard of the European ones, subject to rules similar to those prevailing abroad. This would mean independence of the springs themselves from the hotels, all possible precautions against contamination and adulteration and the restriction of the use of the waters under supervision of competent and independent physicians. Attractive and healthful surroundings should be provided, together with arrangements for patients to take the cure at an expense graded according to their means. The author doubts whether all this can be brought about without State control.

Splenic Anemia.—H. L. Hull reports a case of splenic anemia differing from the ordinary run of cases. The special features to which he calls attention are the absence of hemmorrhages from the mucous membrane, which are so common in the reported cases, and the presence on several occasions of an excess of eosinophiles, of myelocytes, and nucleated red cells. The irregular and elevated course of the temperature for a period of at least three months and continuing until the time of the report is also noted as unusual.

Pruritus Ani.—D. H. Murray states that pruritus ani is caused by an infection by or associated with one of the streptococci group, which may be the primary, secondary, or aggravating cause; if it is the secondary or aggravating cause, the primary cause may already have passed away. Whether the infection occurs because the opsonins for streptococci are low or whether the opsonins are les-

sened because of the invading organism is not yet known. If the opsonic index is low for *B. coli*, or any other bacteria, there may be a complicating infection. A vaccine made from a culture of the offending germ offers the best hope of cure. Whether any local treatment for temporary relief, while awaiting the results of vaccine treatment, is advisable or not must be left to the judgment of the attending surgeon. Some of the cases detailed by the author were treated only with autogenous vaccine, and the results were as satisfactory as in those cases receiving topical treatment as well.

Unicellula Cancri: the Parasite of Cancer.—By Sir Henry Butlin. (See MEDICAL RECORD, December 16, 1911, page 1229.)

First and Last Kink in Chronic Intestinal Stasis.—W. Arbuthnot Lane calls attention particularly to the last kink which affects the large bowel where it crosses the brim of the true pelvis on the left side. This kink develops very early in life, and is caused by a band which develops before the erect posture is assumed, in order to resist the tendency to the downward displacement of the large bowel into the true pelvis. As this new band or mesentery contracts and becomes a definite ligament quite distinct from the normal mesentery, on whose outer aspect it exists, it fixes the large bowel securely at this level. It is so arranged as to oppose the backward passage of feces from the pelvic colon upward into the large bowel. The author believes that no one can become affected by tuberculous disease or by rheumatoid arthritis unless the resisting power to the entry of microorganisms has been depreciated by autointoxication consequent on the presence of chronic intestinal stasis. So in these conditions, and especially in the case of progressive tuberculous affections of joints, he employs no local operative procedure on the affected joint other than rest, and, if necessary, aspiration of any fluid material that does not readily become absorbed after the operation, but proceeds to free the patient of the autointoxication by putting the ileum into the pelvic colon below the kink at the brim of the pelvis. In these cases the results of the operation have been most successful. There is also an obstruction that frequently develops in the end of the ileum and which plays an important part in the production of the group of symptoms which are regarded by the physician as evidence of indigestion. Besides the minor effects of the damming back of contents resulting from this kink there is the development of the duodenojejunal kink, the dilatation and inflammation of the duodenum and of the stomach, which not infrequently leads to the development of cancer of the latter organ, and the infection of the biliary and pancreatic ducts, followed by the formation of gallstones, pancreatitis, and by cancer of the biliary ducts and pancreas.

Association of Hysteria with Malingering.—F. Parkes Weber presents phylogenetic conception of hysteria as an exaggeration or disorder of the so-called tertiary sex characters. By the latter is meant those characters dependent on the nervous system, including both characters of instinct and characters of mind. The functional paralyses and hysterical pains and paresthesiæ may be regarded as exaggerations of the slight ailments to which the "weaker sex" are supposed to be naturally more liable and which call for the sympathetic interest of the protecting males. The hysterical disorders of the circulatory system may be regarded as representing an exaggeration of the normal vasomotor excitability of young females. Hysterical deception or mythomania is an exaggeration of an instinct that has developed in the female from prehistoric times, and that has enabled her to protect herself from the stronger males, and to attract her partner.

Acute Osteomyelitis of the Spine.—F. Fraser and T. McPherson report a case of this condition in a boy nine years of age. The subjects of the disease are generally under the age of twenty, though occasionally it occurs in persons over middle age. In most instances there is a history of some slight injury such as a blow or strain, and sometimes some local cause of sepsis, such as furuncle, is present. The onset is accompanied by high fever and very severe local pain. Rigidity and tenderness of the spine are usually present, sometimes retraction of the head, or opisthotonos. It is said that jarring of the spine does not produce pain as it does in Pott's disease. Abdominal pain and distention are nearly always present, and may lead to much difficulty in distinguishing the disease from some acute abdominal condition. The nerve symptoms, when fully developed, are those of pressure on the cord at the segment affected—viz., root-pains with paralysis, and exaggerated reflexes below. Unless early relief is given by operation, these cases rapidly go from bad to worse, and are characterized by continued high fever, rigors, splenic enlargement, formation of abscesses in situations varying according to the locality of the lesion, visceral complications, and pyemia. The disease has been mistaken for typhoid fever, pneumonia, peritonitis, and acute spinal meningitis. The outlook is always grave, the mortality being estimated by different writers at from 60 to 75 per cent. The only possible chance of recovery must lie in early diagnosis and prompt operation.

Bullet Removed from Metatarsal Bone.—J. P. Christopherson reports the case of the removal of a lead bullet from a metatarsal bone of a man, twenty-three years after the bullet had been received in battle. During this time it had caused no trouble.

Lymphatics of the Scrotum.—J. Morley states that, in consequence of the very free anastomosis between the superficial lymphatic network of opposite sides, it is obvious that whenever an epithelioma approaches the median raphe the glands of both groins must be removed. In view of the termination of the medial trunks from the anterior surface in the superoexternal glands, it is important that, when a growth approaches the anterior raphe, the subcutaneous tissue and glands should be removed to within one inch of the anterior superior spine of the ilium.

Systolic Blood Pressure in Diseases of the Heart.—V. T. Korke concludes that in valvular lesions of the heart (with or without complications), due to rheumatic endocarditis and other causes, the blood pressure is found to be normal or above normal. In aortic incompetence complicated with anginal attacks, the blood pressure is subnormal during the interparoxysmal periods. The low systolic blood pressure is, perhaps, an expression of the failing power of the myocardium. The high blood pressure observed in some of the cases of simple uncomplicated rheumatic valvular lesions is a physiological compensation, though it may be mistaken for a pathological state. The blood pressure in cardiac muscle failure is normal or well above normal, as the result of various pathological causes which produce a change in the myocardium.

Specific Gravity of the Blood.—A. Ross notes that usually the specific gravity of the blood has not much importance from the clinical point of view. One is, however, impressed by the important part which the determination of the specific gravity of the blood plays in the treatment of cholera. That a parallelism exists between the specific gravity of the blood and the hemoglobin content of the red cells is well known, and both Hammerschlag and Schmaltz have constructed tables showing the percentage of hemoglobin corresponding to different degrees of specific gravity.

Unicellula Cancri: the Parasite of Cancer.—By Sir Henry Butlin. (See MEDICAL RECORD, December 16, 1911, page 1229.)

Pituitary Growths.—J. J. Evans classifies the manifestations of pituitary neoplasms under the two groups, hyperpituitarism and hypopituitarism. These two classes of symptoms may be due to prevented action of the hyphophysis or to prevented action and interaction of several ductless glands (polyglandular syndrome). Under hyperpituitarism are included acromegaly and gigantism. According to Brissaud and Meige "gigantism is the acromegaly of the growing period; acromegaly is the gigantism of the period of completed development; acromegalogigantism is the result of a process common to gigantism and to acromegaly, overlapping from the period of adolescence into that of maturity." The essential feature in each case is exaggerated growth of the skeletal tissues, hard and soft, especially of the extremities, associated with alteration in the physiognomy and in the contour of the skull. The symptoms which may be ascribed to the mechanical effects of the intracranial tumor may include headache, vomiting, vertigo, tinnitus, polyuria, or glycosuria, convulsive or apoplectic attacks, and certain psychoses, including delirium, delusions, perverted or excessive appetite, and melancholia. Mental and physical torpor are often complained of, and whereas the pulse may be accelerated the temperature of the body is lowered. The localizing symptoms of the intracranial growth are mainly exhibited in connection with the eyes and the ocular muscles. Impairment of vision in one or both eyes is often complained of, and in cystic or vascular tumors, which may vary in size or burst, the vision may be definitely variable. The impairment of sight may be associated with the appearance of a blue haze over everything. As a general rule the impairment of sight slowly but surely progresses to almost complete blindness. Alterations in the visual fields are a striking feature of pituitary enlargements, and bitemporal hemianopia is the most common and most characteristic of these alterations. Under hypopituitarism are included the cases of retarded skeletal development designated ateliosis, and also certain cases of excessive development of fat with mental and physical torpor, and disturbance of sexual functions—dystrophia adiposogenitalis of Fröhlich.

Vaccine Treatment of Gonococcal Arthritis.—R. Stockman has found that the administration of dead gonococci exerts no curative influence in gonococcal arthritis.

The Albumin Reaction in Pulmonary Tuberculosis.—N. Raw states that in the large majority of cases of pulmonary tuberculosis the reaction is easily obtained, and out of the ninety cases which were diagnosed as pulmonary tuberculosis, seventy-five gave a positive reaction and fifteen gave a negative reaction. The latter fifteen cases presented the physical signs of tuberculosis with a positive von Pirquet reaction, but in nine of the cases no tubercle bacilli could be obtained. In six cases, however, tubercle bacilli were found ,and this test was found to be negative in these cases. In the cases of penumonia in the acute stage the reaction is generally positive, although in one case the reaction was not present until the sputum became rusty. In chronic bronchitis and emphysema the reaction is usually negative. In the two cases of tuberculous joints the reaction was negative, and in one case of neurasthenia without lung symptoms the reaction was positive.

Poliomyelitis.—S. C. Hounsfield reports an epidemic of this disease in Howmarket. He believes that it is possible for flies to carry infection from sewage, refuse, or other dirt to food and thence to the alimentary canal, or, at any rate, for infective dust to enter through the same channel.

Ophthalmo-Reaction in Pulmonary Tuberculosis.—A. S. MacNalty states that a negative reaction does not exclude tuberculosis, while a positive one may be present in cases in which no evidence of tuberculosis exists. The reaction appears, however, to be an adjunct to the other methods of diagnosis of tuberculosis.

Pachon's Sphygmooscillometer.—H. L. Watson-Wemyss notes that the readings obtained with this instrument are considerably higher than those obtained with the Riva-Rocci apparatus.

Berliner klinische Wochenschrift.

November 27, 1911.

Abortive Treatment of Syphilis with Salvarsan.—Géronne and Gutmann give their experience with attempts to abort syphilis with 606. It must be borne in mind that, with few exceptions, excision of the chancre has not proved abortive—even when the sclerosis is in its earliest formative period. The attempts to abort with Hg also succeed in but a limited number of cases and even the association of the two abortive resources does not give us any degree of confidence in the outcome. The authors have injected salvarsan into subjects comprising two classes; first, with positive Wassermann already accompanying the chancre and, second, with negative reaction present, the positive phase being as yet undeveloped. The results were brilliant. Of 20 cases of the latter type the Wassermann reaction failed to appear in 17. In 17 cases in which the positive reaction was already present 8 never developed symptoms. The observation periods were long, abundantly sufficient for the development of constitutional symptoms—one year being the shortest. Thus at least twenty-five people were prevented from having syphilis and the author adds a few others entitled to be regarded as aborted cases. Now that the preventive power of salvarsan has been shown, it behooves the practitioner to examine the first suspicious erosion following coitus for spirochetes; for it will no longer answer to await a Wassermann reaction. This employment of salvarsan may be associated with the inunction of mercurial ointment, especially in Wassermann-positive cases. The greater the age of the sclerosis the more urgent the indication for Hg. One thing only we cannot state, to wit, that gummata and metasyphilitic affections will never develop.

Demonstration of the Diphtheria Toxin in the Blood.—Aaser has experimented with Römer's diphtheritic cutaneous reaction and is able to vary the claims put forth. In a boy aged 10 years with toxic diphtheria who had received 8,000 units of antitoxin an attempt was made to determine whether or not the toxin was still circulating in the blood. Some of the latter, withdrawn before the in-

jection, was centrifuged and its serum injected into the skin of guinea-pigs in various quantities. The characteristic necrosis developed. Some 60 hours after antitoxin injection the test was repeated and proved negative throughout. In a second case, which ended fatally, it was correspondingly shown that neutralization had not occured. The first onset had yielded but more toxin was evidently formed in the throat and the subsequent attempt at neutralization proved incomplete.

Streptomycosis Oris Febrilis.—Fleischer believes that he has discovered a new disease to which he gives the preceding name. He has been seeing cases of it for the past 10 years. His first observation was as follows. A young woman was taken with a chill, fever, and slight angina, profuse perspiration—like that of acute rheumatism—being a special feature. There were no further symptoms, but it was learned later that a delicate false membrane was present on the gums. This seemed to be the source of the constitutional reaction. Similar cases seen afterward gave opportunity for bacteriological tests, and the membrane was found to contain streptococci. In some cases the fauces, soft palate, and uvula presented the delicate membrane, which occurred, for the most part, in discrete points which, while closely aggregated, showed little tendency to coalesce. The constitutional symptoms showed no uniformity. The formation in some cases was associated with acute articular rheumatism; in others meningeal irritation; in others perityphlitis, etc. The condition may, of course, be regarded as an expression of streptococcus sepsis of unusual mildness and unusual origin. In ordinary sepsis of oral origin we should expect to find deep ulcers, but here there was no formation whatever of pus.

Münchener medizinische Wochenschrift.

November 14, 21, and 28.

Action of the Peristaltic Hormone on the Blood Pressure.—Dittler and Mohr have made the discovery that in sufficient dosage the peristaltic hormone of Zuelzer causes marked lowering of blood pressure, and believe that this activity may throw some light on the nature of hormone action. They were engaged at the time in a research as to whether or not the peristaltic action was a truly specific one, it having been asserted that various other organ extracts possess this property. Experiments with Witte's peptone show that some connection may exist between lowering of blood pressure and peristalsis. In animal experiments every intravenous injection of the hormone is followed at once by lowering of blood pressure, while the peristaltic action may not be in evidence for some hours. The connection is therefore not clear. In the human subject a therapeutic injection of the hormone caused collapse, the blood pressure falling from 125 to 100. The patient had developed paralytic ileus after pneumonia and nephritis.

The Fever Which Follows Intravenous Injections.—Heubner refers to the pyrogenetic power of physiological saline solution when injected intravenously as a specific activity of the sodium ion. The same result does not occur when Ringer's solution is used. Another cause of temperature rise has been found in the mere presence in the blood of minute colloid particles of any substance foreign to the organism. This has been studied recently in brass molders, who are subject to a malaria-like affection due to the inhalation of minute particles of zinc, which appear to be able to enter the blood from the air cells. It has therefore been thought possible that malarial fever itself may have a mechanically operating cause in the gymnospores. The author has shown the reality of this corpuscular fever by injecting fine suspensions of paraffin. The fever which follows intravenous injections in general may hence be sometimes accounted for without invoking the presence of an anaphylatoxin.

Spontaneous Recovery in Sinus Thrombosis.—Haymann has shown that spontaneous cure of sinus thrombosis may occur and the inference is that this termination is by no means rare. Even with the primary otitis media persistent, the obliterated sinus may not only undergo resolution but may in a sense again become permeable to blood. The author claims to have for the first time secured complete histological proof of these salutary changes. Replying to the possible criticism that the sinus thrombosis may not have been otogenous he states that he successfully excluded all other possible causes. The exclusion was not only made clinically but to a large extent on anatomical grounds as well.

Recovery in a Case of Rhinogenous Abscess in the Frontal Lobe.—Butzengeiger reports a case of this termination, which should make the total number twelve. Patient was a boy aged twelve. The source of infection was an abscess of the frontal sinus, which, although it broke externally, nevertheless managed to infect the brain. In this respect the case appears to be unique. There was also a double relapse during the management of the case, requiring in all three separate operations. In both interventions for relapse it was necessary to remove notably large portions of prolapsed brain substance, it having been shown that such removal is not prejudicial to the subsequent perfect functioning of the brain. The very unfavorable prognosis in these abscesses in comparison with that of otogenous abscesses appears to be due chiefly to imperfect facilities for drainage.

Intermittent Limp.—Erb has continued to collect statistics of this complaint with especial reference to the smoking habits of victims. All but 7 per cent. used tobacco and nearly 80 per cent. were heavy smokers. Other causal factors seem much less significant—syphilis, alcoholism and exposure to cold. It is also evident that tobacco does not exert its pernicious influence in the same direction. In addition to various types of arteriosclerosis it seems to cause a severe vasomotor neurosis and thus is able to produce two difficult types of the limp. Erb was able to show that an acute arteritis of the femoral disappeared when tobacco was discontinued

Salvarsan in Minute Doses.—Waelsch concludes that salvarsan may produce its favorable results in very small doses. This was noted especially in syphilis of the labyrinth. These small doses were able also to cause local Herkheimer's reaction. The author was able to give salvarsan in severe syphilis of the type said by authorities to furnish contraindications.

Salvarsan Cure of Syphilitic Pancreatis and Acute Atrophy of the Liver.—Umber publishes a remarkable cure of a case of visceral syphilis. The lesion of the pancreas set up diabetes. The case was instructive throughout. The male subject contracted syphilis at the age of 47. He had always been healthy and during a year of syphilis had received proper treatment. He was attacked by gastric symptoms and jaundice and passed fatty matter by the bowel. The pancreas enlarged and diabetes set in. The fatty stools continued and so much fat was present that it formed a thick layer which solidified on cooling. Soon after salvarsan was exhibited the pancreatic symptoms showed improvement and patient made a good recovery. In regard to the acute yellow atrophy diagnosticated, the diagnosis seems to have been made from the character of the stools to the uterus and physical signs and also from the not infrequent occurrence of this lesion in syphilis (the author has personal knowledge of fifty cases). The urinary picture was not that of hepatic insufficiency. The author made autopsies in a number of cases of acute yellow atrophy in syphilitics and also treated cases which recovered. One can only explain the incomplete picture of acute yellow atrophy in his case by the prompt curative effects of the salvarsan before the hepatic parenchyma broke down.

Objective Findings in Spastic Constipation.—Singer and Holzknecht gave cylsmata of bolus alba in aqueous suspension and took radiograms of the colon of normal subjects and victims of spastic obstipation. They conclude that in the great majority of cases there is a high degree of hypertonicity of the distal segment of the colon, while the proximal segment shows for the most part normal tonus and increased motility. The boundary between the two segments is not always in the same locality, but always lies somewhere between the right flexure and end of the descending colon. At the sigmoidorectal angle is to be found a spastic intermission. Its demonstration is not always successful.

Scarlatinal Nephritis. — Leede believes that the scarlatinal virus injures every kidney to a greater or less extent, just as it injures the liver (urobilinuria) and skin (Rumpel-Leede phenomenon). This injury does not, in itself, constitute a nephritis or lead to one. This develops when a predisposition exists—a congenital or familial insufficiency; so that we may see nephritis at times with scarlatina of the mildest course. The Wassermann reaction is twice as often positive in scarlatinal nephritis as in scarlatina without nephritis; and it is possible that in general a positive Wassermann means that parenchymatous organs are involved. Nephritis *per se* has no significance in the reaction. There is a possibility of remote ancestral syphilis in scarlatinal nephritis, but this has not in any sense been shown to exist.

Reciprocal Relations Between Filling, Form, and Site of the Stomach and Colon.—Groedel and Schenck find that when the stomach is distended the position of the colon is but little altered. An exception is found in the left flexure, which is sometimes forced backward. The stomach is influenced by any sort of colonic distention—gas, feces, enema. If a segment of the transverse colon is distended the stomach is indented or displaced laterally. If the entire transverse colon is distended the stomach is elevated. In ptosis or pathological distention of either organ these effects are enhanced. It is, therefore, necessary to evacuate the colon before a pyloroptosis or gastrectasia can be made visible. A thorough emptying of the colon should, however, be practised in all *x*-ray work.

Fatal Familial Angioneurotic Edema.—Harbitz reports a case of fatal edema of the face and throat. The patient's father and grandfather had died the same death. Enough cases of this familial type are on record to make a total of 170, of which number no less than 36 ended fatally through edema of the larynx. In addition to the three fatal cases in patient's family other members were sufferers from the affection. The trait inherited appears to be an anaphylaxis to some unknown substance. Aside from the ordinary angioneurotic edema of the face and extremities it may be expressed as effusion into a joint. And in addition to these massive types there are, no doubt, other recurrent affections due to slight, almost imperceptible, edema.

Deutsche medizinische Wochenschrift.

November 30, 1911.

Crossed Toe Reflex.—Maas states that in healthy subjects we see, as a rule, no crossed toe reflex. We do see at times bilateral crossed reflex in subjects with heightened reflex irritability. The unilateral crossed reflex, if no organic nerve disease is present, is seen only in subjects with advanced tuberculosis. When the latter can be excluded, the unilateral reflex indicates organic changes in the central motor neuron, and is also found in cases with Babinski reflex absent. The symptom, therefore, presents clinical interest. It is often the earliest evidence of beginning spastic paralysis. The autho, who was the first to call attention to this reflex, refers to the sluggish dorsal flexion of the great toe of a paralyzed limb which follows irritating the sole of the sound foot.

Venesection and Saline Infusion in Dermatological Practice.—Simon believes that one has a valuable addition to the armament of the dermatologist in Bruck's method. It is especially indicated in the toxicodermatoses, which include forms of chronic pruritus, urticaria, furunculosis, pemphigus—in short, wherever we have reason to suspect the presence of a toxin in the blood. Pruritus is often the essential cause of eczema. The author has thus far treated in this manner 100 cases of skin disease. The most brilliant results were obtained in generalized pruritus, and the next best in urticaria. The author withdraws from 100 to 200 c.cm. of blood and injects through the same cannula from 300 to 700 c.cm. of 0.9 per cent. sterile saline infusion.

The Nucleoproteid of the Thyroid Colloid in the Treatment of Graves' Disease. — Tschikste of Prof. Kocher's clinic has employed this substance hypodermically for typical Basedow's disease, obtaining it from large colloidal goiters removed at the Berne surgical clinic. The substance was prepared according to Oswald's method. It seemed to exhibit a distinct antagonism to the thyreotoxic principle, and so modified the metabolism as to increase the retention of N and phosphoric acid. It naturally contains phosphorus itself, perhaps as an indispensable constituent of an enzyme substratum. The phosphoriferous substance of the thyroid may be said to antagonize the iodine-containing component—the former heightens unduly while the latter retards undue metabolism.

Salvarsan in Japan.—Dohi and Tanaka of Tokio, who have tested salvarsan for a year, are enthusiasts in regard to the abortive and curative power of the latter in syphilis. They even pronounce it to be an ideal remedy. They use chiefly the intravenous method and administer Hg in combination. They state, on the other hand, that salvarsan should be given at certain intervals during months and perhaps years, just as we give mercury. When given for other diseases of whatever kind, the results were negative, save in cases amenable to ordinary arsenical medication.

Diagnostic Significance of Diastase Excretion in the Urine.—Marino notes that the urinary excretion of diastase is diminished in diabetes mellitus, nephritis, and in pernicious and secondary anemia. It is increased in diseases of the pancreas.—*Deutsches Archiv für klinische Medizin.*

Qualifications for Military Aviators.—A special aviation corps has been established in the Italian army, and in connection with it Dr. M. Falchi, one of the military surgeons attached to the school of aviation, has published the following as his idea of the qualifications of a military aviator: Officers are best between twenty-five and thirty-five years of age. Under twenty-five men are apt to attempt senseless and foolhardy flying; over thirty-five, they may be more susceptible to the dangers of aviation, because of the beginning senile changes in circulatory and respiratory apparatus. They should be light in weight, weighing about 165 pounds; they should not, however, train excessively for the mere purpose of reducing weight. They must be of robust physique, should not be alcoholic, and have no inherited tendency toward epilepsy or other nervous disorders. They must have excellent vision and hearing, and no disease of circulatory or respiratory organs. They should be of even character, being neither emotional nor hesitating. They should be prompt in obedience as well as in command. They should, finally, be intelligent persons.—*Giornale di Medicina Militare.*

Insurance Medicine.

THE MORTALITY OF ALCOHOL.

The effect of alcohol upon the mortality figures of a community has become a threadbare subject in speeches and writings of prohibition and anti-prohibition publicists; yet, indeed, few subjects of sociological nature deserve more frequent mention. The trouble has been, however, that such mention was rarely, if ever, founded upon a real study of the subject, but was simply an indicator of the intolerance of the defenders of one or the other political or social creed. There is no question that for men interested in insurance matters the problem of the "mortality of alcohol" is one of foremost rank, and it is to their credit that one of the best scientific studies* of the matter that has yet appeared comes from one of their number. Mr. Phelps, who has published several statistical studies in similar fields, has taken the total adult mortality in the United States for the year 1908 as the groundwork of his study. His method was simple: he obtained from the medical directors of three large insurance companies their estimate of the percentage of male deaths between the ages of twenty and seventy-four, directly or indirectly due to alcohol, for each of the 106 causes of death listed in the census statistics for that year. From these estimates he figured the probable mortality from the same cause among females, and then made an approximation of the probable total mortality ot the entire country, including the so-called non-registration area, from which direct mortality statistics were not available. In defense of this method of study it may be granted that medical directors of insurance companies have much broader knowledge of the general subject of mortality and the effect upon it of certain specific causes than even the busiest and most prominent of practitioners of medicine. Moreover, the differences in the individual estimates were such as to lead to the reasonable conclusion that a poll of, say, several hundred physicians would not have resulted in a nearer *average* approximation than the average obtained from the poll of these three physicians only.

Before stating the results of Mr. Phelps's study it may be of interest to name the various estimates previously made. Mr. G. Archibald Reid, in his work "Alcoholism—A Study in Heredity" places the mortality from the use of alcohol in the United Kingdom at "about one-sixth of the total mortality from all causes," or at more than 16 per cent.! The Rev. Christian F. Reisner, in a speech from the pulpit of the Grace Methodist Episcopal Church of New York, is reported to have said that "liquor kills 440 out of every 1,000 every year," or 44 per cent.! Without going into minute analysis of the methods used by Mr. Phelps, we may state that to a disinterested mind his use of the statistical tables seems to be quite correct from the standpoint both of statistical science and of every-day methods of arriving at approximations. His final result is that 66,000 deaths was the mortality directly or indirectly due to alcohol in this country during the year 1908, or in percentage figures, about 5 per cent. of the total mortality from all causes at all ages during that year.

*The Mortality of Alcohol: A Statistical Approximation of the Deaths in the United States in Which Alcohol May Figure as a Causative or Contributory Factor. By Edward Bunnell Phelps, M.A., F.S.S. New York: Thrift Publishing Company, 1911.

This, then, forms the first scientifically constructed approximation of the effect of alcohol upon mortality in this country. To the rabid prohibitionist it will, of course, appear to be too low a figure. To the medical man, however, this figure is large enough to prove the appalling waste of life due to the excessive use of alcohol. Moreover, no mere mortality statistics can give an idea of the economic waste due to loss of working time and of productive efficiency among habitual and heavy drinkers, and the daily scenes in our courts of law, both low and high, are but an indication of the number of crippled and unhappy lives which result from the abuse of alcohol.

The whole subject of alcohol is a borderland problem between medicine and sociology. As a medical man the physician must defend the use of alcohol in medicine, as a drug and as a vehicle in the preparation and administration of drugs; he must work at the task of preventing or curing chronic alcoholism by better methods than are at present available. As a citizen the physician must lend the weight of his word and vote to such measures as will diminish the rôle of alcohol as a solace to the poverty stricken and the downtrodden. Mr. Phelps's study gives the firm foundation by which any future results of such activities may be studied and measured.

A Suggested Readjustment of Our Views on Heart Examination for Life Insurance.—By Chas. F. Martin, M.D., Montreal, Canada. (See page 1259.)

Medical Section of the American Life Convention.—The midyear meeting of this society will be held at San Antonio, Texas, on Wednesday, Thursday, and Friday, February 28 and 29, and March 1, 1911. The headquarters of the section will be at the St. Anthony Hotel, where rooms can be had at prices ranging from $1.50 per day for a single room to $4.00 per day for a double room with bath, for two persons; these prices are for rooms which do not look onto the park. It is suggested that those who expect to attend the meeting secure their hotel accommodations in advance. The railroad fare from Chicago is $48.50 for the round trip; from St. Louis, $37.50. The chairman of the Medical Section is Dr. Ambrose Talbot of Kansas City, Mo., the secretary is Dr. F. L. B. Jenney, Marquette Building, Chicago.

Pleurisy and Insurance.—Bourgy says that pleurisies the cause of which can be well established, or such as are simply complications occurring in the course of other acute diseases, in a word, non-tuberculous pleurisies, are not contraindications to acceptance for insurance, if the following conditions have been fulfilled: The cure is complete, as corroborated by freedom from signs and symptoms for a sufficient period of time. There has remained no sequel of the disease that may embarrass other organs in performing their functions. The same attitude should be adopted in regard to empyema, even though surgical interference has been necessary for effecting a cure. So-called essential or primary pleurisy, on the other hand, must be looked upon from a different point of view. It is usually due to tuberculosis, and the applicant giving a history of such pleurisy must be thoroughly examined with regard to any manifestations of tuberculosis. Personal and family antecedents, age, sex, surroundings at home, profession, habits, date of the pleurisy, etc., are the points which must be fully considered. Whenever there is any doubt it is always a good general rule to recommend postponing the acceptance of the applicant for a fairly long period of time.—*Third International Congress of Insurance Physicians.*

Book Reviews.

The Healer. By Robert Herrick, Author of "Together." Price $1.35. New York: The Macmillan Company, 1911.

In this age of muck-raking the physician has come in for his share of calumny. Neither the crude gibes nor the venomed discourses of the popular writer have succeeded is presenting a caricature of the medical man as huge and unreal as that portrayed in this novel. The author has chosen as his hero Eric Holden, a morphine-habitué, who retires to the Canadian woods to conquer his ailment by dint of hard work in the practice of medicine among the lumbermen. Although skilled in the modern development of his art, he gains repute by employing the methods of psychotherapy. He scorns the business foresight of the city physician, nevertheless this does not prevent him ultimately from amassing wealth in the primitive spa which he establishes about his "Healing Spring." He marries a city girl whose life he has saved by a timely surgical operation; but in a few years he deserts her and his children. A combination of savage and savant, his taciturnity, bad manners, and indifference to his nearest kin, make him a most repulsive type, whose sharp features are not relieved by his better traits. The author is apparently pained at the thought that certain practitioners make more than a bare living, for he preaches the doctrine of nationalizing the practice of medicine. He would have physicians in the employ of the State, which would also conduct all medical research. If this volume is meant to be a criticism of modern medical practice, it is neither clever nor enlightening. Its dialogue is insipid, its allusions are commonplace, and its realism is indelicate. The book, unfortunately, will be widely read.

The Fourth Physician. A Christmas Story. By Montgomery Pickett. Illustrated by Gordon Stevenson. Price, $1.00. Chicago: A. C. McClurg & Co., 1911.

This is a short and well-written story about doctors. There is Dr. Frederick, the kind-hearted country practitioner, who would miss his Thanksgiving dinner to respond to a charity-call ten miles over the Virginia roads, in a pouring rain. Another type is Dr. Warren, the self-sacrificing worker in the slums. Then there is the hero of the story, Dr. Livingston Shepherd, the fashionable and exclusive children's specialist, whose engagement to announce his important "discovery" before the medical society makes him deaf to the pleading of his sweetheart to save the life of a dying child by the administration of his "specific." His heart is finally melted by the spirit of Christmas, but too late to save the child. Repentant, he bows before the venerable negro servant as the latter delivers these inspired words: "Can't you see, sah? *You* wah de patient, an' you am *healed!* You is made *de one great* discov'ry!" The devotion to science and to a rich clientèle had sclerosed the instinct of humanity which finally softened under the ministration of the fourth Physician.

Diseases of the Skin. By James H. Sequeira, M.D. Lond., F.R.C.P. Lond., F.R.C.S. Eng. Physician to the Skin Department and Lecturer on Dermatology at the London Hospital, in charge of the Queen Alexandra Department for Light Treatment; Hon. Secretary of the Dermatological Section, Royal Society of Medicine; Editor of the *British Journal of Dermatology*, formerly Physician to the North-Eastern (now the Queen's) Hospital for Children. With 44 plates in color and 179 other illustrations. Price $8.00. Philadelphia: P. Blakiston's Son & Co., 1911.

Sequeria has designed his book chiefly for the use of the student or the general practitioner and has certainly succeeded in producing a very valuable volume. He has utilized all modern developments in dermatology to classify skin diseases on etiological lines and, where this is impossible, on morphological characters. The book, therefore, reads more like "systematized knowledge" which a textbook should be, than a dictionary of names and lesions which many dermatological books resemble. Historical references and weary discussions of debated points have been omitted and more room has therefore been gained for discussion of diagnosis and treatment. The latter topic has been brought up to date and very valuable information is given by the author in regard to the use and effect of *x*-rays, radium, light, Ehrlich's salvarsan, etc., etc. This information, too, is founded on the author's personal experiences, as shown by the numerous photographs presented, and not upon a mere compilation of literary data.

The distinguishing value of the book, however, lies in the number and the character of the illustrations. The usual photographs are marked by distinctness and objectiveness, that are often sadly lacking in pictures of skin lesions; most remarkable, however, are the plates which represent photographs in three colors taken directly from patients by Dr. Arnold Moritz. We have never seen better pictures of this character, and can only express the hope that future editions of the book may be enriched by more plates of similar type.

The work is heartily recommended to the American reader as the best of the recently issued textbooks on diseases of the skin.

A Manual of Clinical Diagnosis. By Means of Laboratory Methods, for Students, Hospital Physicians, and Practitioners. By Charles E. Simon, B.A., M.D., Professor of Clinical Pathology and Experimental Medicine at the College of Physicians and Surgeons; Pathologist to the Union Protestant Infirmary and the Hospital for the Women of Maryland; Clinical Pathologist to the Mercy Hospital of Baltimore, Md. Seventh Edition, enlarged and thoroughly revised. Illustrated with 168 engravings and 25 plates. Price $5.00. Philadelphia and New York: Lea and Febiger, 1911.

Dr. Simon's Clinical Diagnosis has been very well known and highly appreciated by medical students and members of the medical profession for a considerable period of time. The present work has been brought up to date and besides inaugurated a new departure. In the first instance a great deal of material which had been included in the former editions has been eliminated, the author deeming it superfluous matter or rather matter out of place. This decrease of material rendered it possible for Dr. Simon to so draw up the plan of the book that the exposition of laboratory methods of diagnosis and the applications thereof have been arranged systematically instead of as heretofore following in somewhat promiscuous order. In order to accomplish this, almost half of the volume has been devoted to the laboratory diagnosis of each disease arranged under its name in alphabetical sequence, thus making the comparison of a case with the diagnostic picture of the disease a comparatively easy task. The present arrangement is: Part I, representing the technical portion, and Part II, the new part, the clinical portion. By judicious elimination, revision, and condensation the contents of the previous volume have been so shaped that while containing all essential information they occupy rather more than half the present edition. It was chiefly to aid the student to interpret correctly laboratory findings that Part II was written, and there is little doubt that it will accomplish this object to a great extent. The Wassermann reaction is described in detail and carefully. The chapter on the blood presents clearly the most modern morphological, biological, and chemical methods. The entire work is well arranged, excellently bound and printed and the illustrations are exactly what illustrations should be—they sufficiently elucidate the text. The book can be conscientiously recommended as, perhaps, the best work in its particular line in print.

Die Wohlfahrtseinrichtungen für Kinder in grossen Städten. Von Geh. Med.-Rat Prof. Dr. A. Baginsky. Nach einem am 6 December, 1910, in der Gesellshaft für öffentliche gesundheitspflege zu Berlin gehaltenen Vortrage. Price 0.40 mark. Berlin: August Hirschwald, 1911.

The supervision of the dependent child is the theme of this address. The most important aspect of this question, as emphasized by the author, is that the public or private efforts to care for the dependent child should not be relaxed before the latter reaches the age of puberty. The eminent German pediatrist discusses this subject with the authority of one who has had ample opportunity to observe the best organized systems of child-welfare work in the world.

Veröffentlichungen der Robert Kochstiftung für Bekämpfung der Tuberkulose. Herausgegeben von Vorstand der Stiftung. Heft 1. Uber den Typus der Tuberkelbazillen in Auswurf der Phthisiker. Von Stabarzt Dr. B. Thällers. Price 3 marks. Leipzig: Verlag von Georg Thieme, 1911.

This is the first number of the publications of the Robert Koch Foundation. It presents the results of an investigation of the sputum of 51 subjects of pulmonary tuberculosis, as to the type of bacillus, bovine or human, contained in the sputum. In no instance was the bovine bacillus isolated. The author concludes that this investigation supports the original contention of Koch, namely, that bovine tuberculosis plays an insignificant rôle so far as human susceptibility to it is concerned.

A Reference Handbook of Obstetric Nursing. By W. Reynolds Wilson, M.D., Visiting Physician to the Philadelphia Lying-in Charity; Member of the American Pediatric Society, etc. Illustrated. Second edition. Thoroughly revised. Price $1.25. Philadelphia and London: W. B. Saunders Company, 1911.

This little book will compare favorably with other and larger works on the same subject. In it the nurse will find all that she is likely to require; and the book is not burdened with non-essentials. This new edition contains a new chapter, on Precipitate Labor. In the preface the author says that "the Appendix has been amplified"; but we are unable to find any appendix to the book.

Progressive Medicine. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Hobart Amory Hare, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College, Philadelphia, assisted by Leighton F. Appleman, M.D., Instructor in Therapeutics, Jefferson Medical College, Philadelphia. September 1, 1911. Price $6.00 per annum. Philadelphia and New York: Lea and Febiger.

In this number of Progressive Medicine will be found the annual review of Diseases of the Thorax and Its Viscera, including the Heart, Lungs, and Blood-Vessels; Dermatology and Syphilis; Obstetrics; and Diseases of the Nervous System. The first articles, by Ewart, will prove of value to all physicians. In Gottheil's contribution will be found a very useful summary of the literature of arsenobenzol (606). The third and fourth sections by Davis and Spiller will be read with interest and profit by all who wish to keep up to date with Obstetrics and Nervous Diseases.

The Practice of Medicine. By Frederick Taylor, M.D., F.R.C.P., Consulting Physician to Guy's Hospital; Consulting Physician to the Evelina Hospital for Sick Children; Physician to the Seamen's Hospital, Greenwich; Examiner in Medicine at the University of Cambridge and at the Queen's University, Belfast; late Examiner in Medicine at the Universities of London, of Durham, and of Birmingham, and to the Royal College of Physicians, London. Ninth Edition. Price $6.00. New York: The Macmillan Co., 1911.

That this work has gone through nine editions renders it superfluous to expatiate on its worth. The present issue has been very thoroughly revised and several new subjects introduced. With regard to the transmission of infectious diseases, the author appears to believe in the theory that fomites may convey infection in certain diseases, for he advises disinfection of whatever clothes, books, room, or furniture the sick person may contaminate. With regard to the paratyphoid infections the account given, as in most books on medicine, is somewhat scant, especially as to the differentiation of these infections, a question which is arousing considerable interest at the present time. The author is inclined to hold with Dr. Sambon's views with respect to the origin of pellagra. In referring to acute poliomyelitis it is stated that the inflammatory change is almost entirely limited to the anterior cornua of gray matter, a view which is not generally held nowadays. Nor is any reference made to the discovery by Flexner of the infective virus. On the whole the work is comprehensive and up to date. The type is rather diminutive and apt to be trying to the eyes. There are sixty-seven illustrations.

The Diseases of Infancy and Childhood. For the use of Students and Practitioners of Medicine. By L. Emmett Holt, M.D., Sc.D., LL.D., Professor of Diseases of Children in the College of Physicians and Surgeons, Columbia University, New York; Attending Physician to the Babies' and Foundling Hospitals, New York; Corresponding Member of the Gesellschaft für Innere Medizin und Kinderheilkunde, Vienna, and Honorary Member of the Gesellschaft für Kinderheilkunde, Germany. Assisted by John Howland, A.B., M.D., Professor of Diseases of Children in Washington University, St. Louis; Late Associate in Diseases of Children in the College of Physicians and Surgeons, New York. Sixth Edition, fully revised. With two hundred and forty illustrations, including eight colored plates. Price $6.00. New York and London: D. Appleton and Company, 1911.

This new edition of Holt's work shows the author's desire to keep abreast with the current progress in pediatrics. The following subjects, among others, have been fully revised: Pyloric Stenosis, Appendicitis, Acute Peritonitis, Endocarditis, and Pericarditis, Cerebrospinal and other forms of Acute Meningitis, Acute Poliomyelitis, Hereditary Syphilis, and Tuberculosis. The most significant change, however, is noted in the section on Artificial Feeding, and a quotation from the edition of 1903 may be placed in juxtaposition to a statement in the present edition to show the great importance of the changes made. That edition said: "The modification of proteids is the most important change necessary in cow's milk, for it is the proteids which give most of the trouble to the infant's digestion." The present edition says: "To the modification of the protein of cow's milk most of the attention was formerly given. The evidence seems conclusive, however, that healthy infants digest this protein without difficulty." These two statements illustrate better than anything else the great impression made by Finkelstein and his school upon the practice and theory of artificial feeding of infants. They are also an argument for the acquisition of the present edition of Holt by all who, as the reviewer, possess older issues of the work. Similar far-reaching revisions are seen in other departments, especially in sections on poliomyelitis and on the treatment of syphilis; in the latter Holt speaks favorably of salvarsan. Many new illustrations have been added, among them *x*-ray pictures of rare bone changes, and old plates have been replaced by new ones.

Food Values. Practical Tables for Use in Private Practice and Public Institutions. By Edwin A. Locke, A.M., M.D., Instructor in Medicine, Harvard Medical School. Price $1.25. New York and London: D. Appleton and Company, 1911.

In this little volume the author gives the necessary information as to the composition and nutritive value of the foods in common use. The book is of more than ordinary value, inasmuch as it is one of the very few that aim at practical utility rather than encyclopedic fullness with corresponding complexity of statement. The book is recommended to the notice of physicians, medical students, and nurses.

Manual of Pathology. Including Bacteriology, the Technique of Postmortems, and Methods of Pathological Research. By W. M. Late Coplin, M.D., Professor of Pathology, Jefferson Medical College, Philadelphia; Medical Director of the Jefferson Medical College Hospital; Pathologist to Jefferson Medical College Hospital and to the Philadelphia (Blockley) Hospital; Director of the Clinical Laboratories of the Jefferson Medical College Hospital; Pathologist to the Friends' Asylum for the Insane, Frankford. Fifth Edition, rewritten and enlarged. With six hundred and twelve illustrations and twelve plates, eleven of which are in colors. Price $4.50 net. Philadelphia: P. Blakiston's Son and Co., 1911.

The changes in the new edition of this well-known manual of pathology have been most extensive. Enough new matter has been added to increase the text by nearly one-fourth and the material has been completely rearranged. On of the new chapters, entitled the "Pathology of Infection," deals with the questions of incubation, defervescence, etc., in bacterial invasion, and another addition of seventy pages is devoted to the pathology of the reproductive organs. Noteworthy changes have been made in the chapters on bacteria as causes of disease, in the internal secretions, on poisons and intoxications, and in many other parts of the book. The appendix contains the sections on technique and among others includes chapters on bacteriological methods, microscopic examination of the urine, and the technique of sputum examination which might perhaps be dispensed with, as they cover subjects belonging by rights to special text books. The work is a highly pleasing one, agreeably written and unusually comprehensive so that it is well adapted to the needs of the student, while the careful and modern bibliographies make it useful as a reference book for advanced workers also. In its new enlarged form it will undoubtedly increase its former success and find a constantly growing field of usefulness.

Refraction and Visual Acuity. By Kenneth Scott, M.D., C.M., F.R.C.S. Edin., Consulting Ophthalmic Surgeon to St. Mary's Hospital for Women and Children, London, E.; Late Lecturer on Ophthalmology, West London Post-Graduate College; Professor of Ophthalmology, Egyptian Government Medical School; and Ophthalmic Surgeon, Kasr-el-aini Hospital, Cairo, Egypt. With sixteen illustrations and a colored plate. Price $1.75. New York: Rebman Company, 1911.

This book has been written for the general practitioner who may feel the need of a more intimate knowledge of the errors of vision and their correction. The author limits himself to the discussion of only the essential points. He divides his book into two parts—Refraction and Visual Acuity. Included in the part devoted to refraction are chapters on the average price of glasses, color blindness, simulated blindness, and the medical inspection of the eyes of school children. The author's style is clear and concise.

Society Reports.

SOUTHERN MEDICAL ASSOCIATION.

Fifth Annual Meeting, Held at Hattiesburg, Miss., November 14, 15, and 16, 1911.

The President, Dr. Isadore Dyer of New Orleans, La., in the Chair.

The scientific work was divided into three sections.

The Stokes-Adams Syndrome.—Dr. J. G. Gaither of Oxford, Miss., after detailing a case that had come under his observation, stated that in the list of reported cases there seemed to be two distinct classes: first, in patients past middle life in whom arteriosclerosis had become pronounced in its effect upon the brain, heart, and kidneys; and, second, a younger class of patients under fifty, usually men, in whom a variety of causes were found. Competent pathologists had frequently made autopsies upon subjects of Stokes-Adams disease, and had failed to find any lesion sufficient to justify the assumption of a causal relation. The prognosis was serious and uncertain. The treatment was purely symptomatic. The subcutaneous administration of a fourth of a grain of morphine was indicated in frequently recurring attacks. The head of the patient should be put low to overcome the cerebral anemia, which was particularly pronounced in a case with the complication of an aortic stenosis. The treatment after the attack resolved itself into the general hygienic and the administration of iodide of potassium. Any particular line of diet which was found to lessen the frequency of the attacks should be followed. Eliminative treatment should be instituted in cases showing a tendency to renal involvement.

Dr. J. B. Elliott, Jr., of New Orleans had seen only one case of Stokes-Adams disease, and this was associated with arteriosclerosis. The patient died in the second attack. Patient was a man, seventy years of age. There was an atheromatous cicatrix found in the bundle of His post mortem.

Dr. J. B. McElroy of Memphis pointed out the importance of distinguishing clinically between two groups of cases, one the cardiac group and the other the neurologenous. Much work had been done with reference to the disturbance of the conductivity of the bundle of His, but undoubtedly there were many of these cases which presented the symptoms of the Stokes-Adams syndrome in which this bundle was not involved. Adami had reported such a case, and the speaker had autopsied one case himself in which the bundle of His was involved and almost completely destroyed by a gumma in which there were no symptoms or evidence of the disease during life.

Dr. J. B. Guthrie of New Orleans had not had the good fortune to see either one of the two diseases described by the essayist, although he had been on the lookout in a large hospital service for the Stokes-Adams syndrome, where the cardionephritic cases predominated.

Dr. Frank A. Jones of Memphis stated that in the last several years he had seen five cases of heart block, three of them in men, and two in women. In nearly all these cases or types of heart block there was pronounced arteriosclerosis. Not only was there pronounced arteriosclerosis, but the arteriosclerosis was accompanied with high blood pressure in contradistinction to arteriosclerosis with a low blood pressure. We did not know what the exact pathology of Stokes-Adams disease or heart block was. He had seen one case with bradycardia with the pulse as low as eight for nearly a week before the patient died in coma instead of a convulsive seizure. In the five cases he had seen there had always been well-defined arteriosclerosis with high blood pressure.

Causal Factors in Malarial Recurrences.—Dr. Graham E. Henson of Crescent City, Fla., reviewed the possible etiological factors in malarial recurrences, the significance of such cases, and considered their treatment. He drew the following conclusions: (1) Parthenogenesis could not be considered a factor in the recurrence of malaria for the reason that the very existence of such a phenomenon was a matter of great doubt, many observers working over a period of years having failed to demonstrate such forms. (2) There were many cases reported that had at no time during the infection shown the sexual forms but had frequently relapsed. (3) The four cases cited by Ross in which inoculation experiments containing only sexual forms failed in each instance to produce clinical symptoms of malaria or to reveal the presence of any plasmodia, while in fifty-one cases cited by the same author inoculation experiments containing the asexual parasites in every instance produced clinical symptoms of the infection and parasites of the type inoculated were demonstrated in all of the cases experimented with since the discovery of the plasmodia.

Pernicious Malaria.—Dr. H. H. Booth of Drew, Miss., reported three cases of pernicious malaria with cerebral symptoms which resembled heat stroke.

Dr. R. H. von Ezdorf of Mobile stated that, according to investigations made in 1898 and 1899, parthenogenesis might have something to do with the recurrent cases of malaria. He had noticed in blood examinations what appeared to have been the conjugate forms. Again, he had observed cases where only the gametes had been present, and he had not been able to find the gametes changed into the form which would revert to the schizodont cycle. In making examinations of the blood of the estivoautumnal cases where the gametocytes were present, he had found that under the specific treatment of quinine the microgametes would disappear in a short time and the macrogametocytes would predominate.

Dr. Louis Leroy of Memphis had not had an opportunity to study parthenogenesis or asexual reproduction, but the resting form mentioned by the essayist had occurred to him a number of times. He had had quite a number of patients who came from latitudes that were considered more malarious than in his section of the country who had in many instances been free from any malarial attacks for a period varying from six months to several years, and invariably after a week in that district outbreaks of malaria would occur. As a matter of curiosity, at the time he examined a dozen or more specimens of blood he failed in many instances to find any parasites, and yet inside of ten days or so apparently new attacks of malaria would be developed. Most of these patients would have enlargement of the spleen develop generally subsequently. Whether or not the spleen or the bone marrow was the site of the resting parasites, which under these changed conditions brought that about, he was not able to say but that was his working hypothesis. He had also brought about paroxysms in one patient following exposure of the enlarged spleen to the *x*-ray, in whom again he was unable to find parasites in the blood. Again, under similar conditions he had seen malarial paroxysms following the administration of large doses of ergot and hydrastin, given with the idea of attempting to reduce the size of the spleen.

Dr. J. B. McElroy of Memphis said that his impressions, as gained from a study of the blood itself and from the literature, were directly in opposition to those of the essayist. He could see no evidence from a study of the blood of these conjugating forms developing in the body. On the other hand, according to the work of Schaudinn, parthenogenesis was a well-established principle. He agreed with Dr. von Ezdorf that the macrogametocytes continued in the blood after the continued and heroic administration of quinine, and he would further say that in the diagnosis of malaria we should not only include the presence of malarial parasites, but the varieties of them,

and we should determine from an examination of the blood whether or not we were dealing with a relapse. This would be easily determined both by the presence of the macrogameotcytes and by the tertiary and the estivo-autumnal types.

Vaccine Therapy in Typhoid Fever.—Dr. J. B. Elliott, Jr., of New Orleans stated that in a series of over two hundred vaccinations among the senior class of Tulane University during the past two years they had had only one case of typhoid fever, which case was proven to have had the infection previous to vaccination. The most remarkable report was that made by Cullinan of an epidemic of typhoid which occurred in an asylum of which he had charge; to prevent its spread Cullinan had inoculated some five hundred who consented and of these only 1.3 per cent. had it, while of the non-vaccinated 14.6 per cent. went down with typhoid fever. In a hasty review of those cases treated with vaccines, he found that Russell had collected 118 cases, with a mortality of 4 per cent. Callison, up to July 1, 1911, had collected 32 cases with a mortality of 5 per cent. Almost every individual reporter had declared that the temperature, course and convalescence had been markedly benefited. Personally, he had treated only three cases. While he fully realized the danger of drawing conclusions from such a very small number of cases, and while he was very conservative, as a rule, in therapeutic matters, yet he had become a little enthused over this method of treatment and should continue to administer the vaccines to all cases of typhoid fever, if seen within the first eight or ten days, and if the practitioner made blood cultures early and often few cases would escape diagnosis in their incipiency.

Dr. A. W. Freeman of Richmond, Va., said it was hardly fair to say that typhoid vaccination at the present time was without danger. In a recent issue of the *Naval Medical Bulletin* the case of a young marine was reported. He was inoculated with the same vaccine that was used in the routine inoculations of the marines of that corps, and who within two or three days developed a most virulent case of typhoid fever and died of it promptly. At the autopsy typhoid bacilli were found in the circulating blood and in the various tissues of the body. Those who studied this case and did the bacteriological work, as well as the clinician, agreed that this young man was in the incubative stage of typhoid fever, and a dose of vaccine was sufficient to overwhelm him and result fatally, when he might have had a case with demonstrable symptoms of the disease. There was no doubt that typhoid vaccination did confer immunity against this disease, but the degree of that immunity had been variously estimated by various experimenters and observers.

Dr. Louis Leroy of Memphis said that, at present, we were suffering very largely from a pernicious activity in pushing and recommending indiscriminately biological products of this nature. It was claimed that negative phases were not as frequent in typhoid as in some other forms of vaccine administration; still with all that, it was calling upon the reserves and without skillful clinical observation we were apt to call out all of our reserves, squander them in an almost helpless charge, and leave the patient helpless in the face of his increasing infection. Dr. Elliott was careful to say that he limited the use of the vaccine to the first ten days. Even at that it would require some discrimination, which he was willing to concede he had, in the administration of this vaccine to all cases. All had seen typhoid patients who were almost overwhelmed from the beginning, and he would question the administration of large doses of vaccine to a patient in that condition. Again, late in the disease it did not seem to be of much use. The main thing he wished to protect against was the indiscriminate use of typhoid vaccines and untruthful advertising of these remedies by therapeutic houses and by detail men who did not know the first principles about it, urging its indiscriminate use in all patients with typhoid fever.

Dr. Charles Le Baron of Gulfport, Miss., mentioned the Spanish-American war, stating that shortly after his return from Chickamauga Park there was quite an epidemic of typhoid fever below this region. Twenty people were exposed to the disease. Every one of them was given typhoid vaccine, and not one contracted the disease.

Dr. Graham E. Henson of Crescent City, Fla., mentioned the case of a man, who, after typhoid vaccination, developed a temperature which varied from 103° to 105°, and was very sick in the hospital for a week. As a prophylactic agent typhoid vaccination was valuable; but the unfavorable results of typhoid vaccination should be reported as well as the successful ones.

Dr. J. B. McElroy of Memphis thought Dr. Elliott should hedge in these good results from typhoid vaccination by a warning or by putting a large question mark against the proposition as to whether or not these typhoid vaccines could be used promiscuously for the prevention of typhoid fever. Theoretically, we would expect that while these individuals were acquiring immunity from one or two doses which had been administered there was a negative phase or sensitization of the individual during which he was more liable to contract typhoid fever than at other times. It was questionable whether we should use these vaccines promiscuously because one or two cases of the disease had occurred in a community.

Dr. R. H. von Ezdorf of Mobile stated that one patient to whom the vaccine was given developed a temperature of 104° which lasted two days. On the second injection the same reaction occurred which did not last quite as long. Statistics showed that we could expect these reactions to take place in about 10 per cent. of the cases.

Dr. Hiram Byrd of Jacksonville, Fla., said that about a year and a half ago they began the administration of typhoid vaccines. They vaccinated 125 people. In two instances the reaction was severe. In a woman the reaction lasted for three days. Aside from these reactions, the results had been very favorable. The youngest child vaccinated was 16 months old. There was a reaction in that instance, as in two other children. They had vaccinated several children under five years of age in whom the reaction had been very slight.

Dr. J. B. Guthrie of New Orleans felt that physicians were perfectly justified in resorting to vaccination as a preventive of typhoid fever when the present condition of sanitation in some of our cities and country towns was considered, particularly where streams were so liable to contamination. Any person whose occupation brought him in contact with typhoid patients, or who was forced to live in a neighborhood where typhoid infection was rife, should be vaccinated against typhoid fever.

Dr. William Krauss of Memphis said one might take it for granted that the German Government would not countenance any system of experimentation with its troops which would prove detrimental to the personnel of the army, and, considering that soldiers were regarded as priceless possessions, no government would permit vaccination against typhoid fever if it was so dangerous as some gentlemen would have us believe it was.

Diphtheria.—Dr. W. W. Harper of Selma, Ala., said that in diphtheria an early diagnosis was essential to successful treatment. Not only could the disease be more promptly cured, but the patient could be spared the complications and sequelæ that followed the delayed administration of antitoxin. As to the treatment, if the patient was seen on the first day of the illness he gave 5,000 units of antitoxin as an initial dose in faucial, and 10,000 units in laryngeal and severe nasal diphtheria. This dose was repeated in twelve hours unless there was marked improve-

ment. He had seldom found it necessary to repeat the dose.

Dr. P. W. Rowland of Oxford, Miss., did not know by what reasoning the author arbitrarily gave 10,000 units of antitoxin in all cases. No rule could be laid down for regulating the dose of antitoxin. It depended largely upon one's habit and practice. He saw no need of giving such large doses. The ordinary dose of antitoxin in any given case of diphtheria was from 3,000 to 5,000 units, and this was found generally sufficient.

Dr. J. J. Stevens of Hattiesburg, Miss., was called to see a case in the night that had all the earmarks of laryngeal diphtheria, but careful inspection failed to reveal any membrane. He gave liberal doses of calomel, left the patient, but was called back early after this and found the child in great distress. The laryngeal symptoms were very prominent. He immediately asked for a consultation and ordered antitoxin. His consultant seemed surprised that he had not administered antitoxin at his first visit. He gave the child a liberal dose of antitoxin some hours after the calomel had been given, and the next report he received was that the child had passed a number of very large worms and was immediately relieved. He thought this case fitted in very well with the essayist's case of appendicitis which was relieved by the administration of antitoxin.

Dr. P. R. Brown of West Point, Miss., emphasized the importance of the early use of antitoxin. He did not believe one would have more than one death in a thousand cases if one used antitoxin within the first twelve or twenty-four hours. He had administered antitoxin to four or five patients within the first twelve or twenty-four hours and had no need to repeat the dose. He generally opened the bowels with calomel and in some cases washed out the throat with an antiseptic solution.

Dr. W. V. Davis of Booneville, Miss., asked whether in giving immunizing doses to members of the family and to others who had been exposed to the disease, any member had noticed urticaria or other skin manifestations.

Dr. John L. Jelks of Memphis stated that in follicular tonsillitis of streptococcic origin, it would be more reasonable and scientific to give some streptococcic vaccine.

Dr. William Krauss of Memphis said we sometimes had diphtheria bacillus carriers that kept up infection for weeks and months, and it seemed utterly impossible to eradicate the infection. It had been found that the application of a pure culture of *Streptococcus aureus* would destroy the diphtheria bacilli in the throats of these patients, and it was the only thing that had been found to do so.

Dr. Harper, in closing, stated that many practitioners did not get results in cases of diphtheria because they did not use large enough doses of antitoxin.

Intubation.—Dr. Joseph J. Waller of Oliver Springs, Tenn., said the two most common types of disease demanding intubation were the severe cases of acute laryngitis and laryngeal diphtheria. This operation had many advantages over tracheotomy. While possibly it might be more difficult and required greater skill for its proper performance, it was not a cutting operation. It was quickly done and was safe.

Dr. W. W. Harper of Selma said he would rather be able to do intubation than to do a cesarean section, for one could oftentimes get competent assistance in performing cesarean section, whereas the country doctor was by himself, in a place where he could not get help, and if he was competent to perform intubation he would save many lives.

Value of the Clinical Laboratory in Diagnosis.—Dr. E. S. Sledge of Mobile drew the following conclusions: (1) Laboratory methods were invaluable in diagnosis, were a great aid in prognosis and in the intelligent observation of the course of the disease. (2) The source and interpretation of the results were of extreme importance. (3) Results were to be considered only as symptoms with the other clinical manifestations of the case. (4) Every physician should do as much laboratory work as was compatible with his time and equipment. For the more advanced work many laboratories were at the disposal of the physician at moderate fees, and provision was made for the transportation of specimens. (5) Every physician should strive to avoid laxness in the employment of laboratory information when occupied by a busy practice and avoid the human tendency to take chances.

Acute Poliomyelitis.—Dr. B. L. Wyman of Birmingham gave the history of epidemics of this disease in the United States.

Dr. E. M. Mason of Birmingham said the virus of poliomyelitis occurred most abundantly in the central nervous system, but had also been found in certain lymphatic glands, and in the nasopharyngeal mucosa. In both man and monkeys one attack of poliomyelitis, even the abortive form, protected against subsequent infection. As to the pathology, the virus became implanted not only upon the leptomeninges throughout the central nervous system, but especially in the region of the spinal cord and medulla, where it set up infiltrative changes that were most marked in the perivascular lymph spaces of the arteries entering the nervous tissues. There was a diminution in the total leucocyte count with a relative lymphocytosis.

Dr. Louis Leroy of Memphis said they had had acute poliomyelitis on the reportable list of the State Board of Health of Tennessee for some time in anticipation of some outbreaks or epidemics within that State. Up to the present time they had only had reported a few scattering isolated cases, but not enough to warrant the name of epidemic at any point. Personally, he had only seen half a dozen cases within the last six years in Tennessee. These cases started with the ordinary symptoms of an infection, with no one definite symptom that he could recall to mind. The cases had all been in children. After detailing the symptoms manifested by these cases, the speaker said that improvement generally began in a couple of weeks after the disease had practically subsided and continued probably under medication, massage, and general treatment for possibly a year. He had seen no marked improvement occur after that length of time.

Dr. W. G. Somerville of Memphis stated that in some epidemics of anterior poliomyelitis there were cases of the cerebral type in which coma came on and lasted for several days, and the patients died or recovered with infantile paralysis. In this type the upper neuron was affected and the patient got spastic paralysis. Some of the cases could not be diagnosed until the paralysis came on, unless there was an epidemic of the disease. The child had fever, convulsions, vomiting, and it was only when the paralysis came on that one was able to make a diagnosis unless he was looking for the disease. In the course of an epidemic, however, when one was on the lookout for such cases, it might be possible, in the early stages, before the paralysis came on, to make a diagnosis by examining the cerebrospinal fluid, as had been pointed out by Flexner.

Dr. Willis C. Campbell of Memphis said the orthopedic treatment of infantile paralysis was very important. There might be a slight weakness of the extremities to a total paralysis of the four extremities. More frequently there was paralysis of both lower extremities. A patient frequently recovered good use of one extremity, while the other remained more or less disabled. Orthopedic treatment should begin as soon as the diagnosis was made. There was nothing that would probably give better results in these cases, Dr. Campbell said, than to begin treatment at an early period and thus prevent deformity from taking place.

(*To be continued.*)

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, Held November 27, 1911.

The President, Dr. James F. McKernon, in the Chair.

The entire evening was devoted to annual reports.

Report of the Counsel.—Almuth C. Vandiveer, Esq., read this report. He submitted a résumé of the work of the legal department for the year; this showed a greater diversity of legal activity for and in behalf of the Society than the records of the past had shown. He commended to the consideration of the Society the following accomplishment in the past year. (1) The decision of the Appellate Division of the Supreme Court defining in unmistakable terms the power and authority of the Society under the charter granted it in the year 1806, and the laws passed by the legislature supplementing the same in the 105 years since its establishment. (2) The determination of the Appellate Division that the $7,500 judgment for malicious prosecution obtained against the Society by an individual prosecuted by the counsel's predecessor, who was acquitted on the charge of illegal practice, should be in all respects reversed, vacated and set aside, and the same was set aside. (3) The challenge by the courts of the rights of so-called faith healers in practicing the healing art in the State of New York under the provisions of the Public Health Law regulating the practice of medicine. In this latter category were Christian Scientists, New Thought advocates, mental healers, and other similar persons claiming to alleviate suffering by methods not included in the curriculum of any medical college in the civilized world. Under the authorization of the Board of Censors the Counsel had made a vigorous attack upon the wealthy and incorporated strongholds of quackery by prosecuting numbers of corporations organized under the Laws of the State of New York and engaged in the practice of medicine through registered physicians. During the pendency before the Board of Censors of charges against a member of conduct unfavorably affecting the character, dignity, and interests of the medical profession, the accused member invoked the aid of the Supreme Court to enjoin and restrain the Society from hearing the charges against him. The learned justice before whom this application came decided that the Medical Society of the County of New York had no authority in regulating the practice of physic and surgery in the State of New York, and had no authority to pass by-laws providing qualifications of applicants for membership therein, and regulating the conduct of members after election. The learned judge further held that no member of the Medical Society of the County of New York could be expelled from membership therein for the commission of any act other than that which would be adjudged under the Laws of the State of New York, a crime punishable by imprisonment in the State prison. This adjudication was presented to the Appellate Division of the Supreme Court and five judges unanimously differed from their colleague of the Special Term and decided that the society had ample legal authority to pass by-laws regulating the qualifications of applicants for membership therein and regulating the conduct of members, and that the society had ample power to expel any member for unprofessional conduct, and intimated that unprofessional conduct of any physician in the county might be a subject of inquiry by this society.

Following up the decision of the Court of Appeals and the prosecution instituted by the society against the Woodbury Dermatological Institute, other corporations of consequence, engaged in the practice of medicine, against which the necessary evidence could be secured, had been vigorously prosecuted. Many of these individuals had ralled to their defense the highest priced and ablest practitioners of the criminal and civil bar.

The work done by the counsel had covered a very wide field, for the persons who strove to practice medicine without the necessary educational and legal qualifications cloaked their actions under many alluring forms of quackery. Not only were the ignorant classes of the community used as a means of livelihood by medical fakirs, but the well-to-do and educated classes were equally imposed upon by persons preaching a doctrine of the superiority of thought and mind over matter and body. It was indeed surprising to know the remarkable following that these persons had among the educated citizens of this city. One person arrested and charged with violating the medical law was reputed to have 2,000 persons in this city as her personal followers.

The counsel of the society had had the honor of presenting violations of the medical law to every judge sitting in the City Magistrates' Courts, and in the Court of Special Sessions. In addition, cases had been presented and considered by several judges of the Court of General Sessions. He felt that the prosecutions brought in the name of the society had received from the courts as serious consideration and as respectful attention as any class of cases presented for their judgment. The Court of Special Sessions inflicted heavier penalties upon persons convicted of violating the medical law than upon any other class of offenders brought before it. A total of fifty-seven cases had been presented during the year. Sentences were imposd in four cases at the time the last annual report was rendered. Thirty-six convictions had been obtained, four persons were acquitted, one died, and twelve cases were still pending. Five cases were now ready for presentation to the courts.

Mr. Vandiveer then gave a more detailed account of a number of the cases that he had worked upon during the past year. Among them was the Collins New York Medical Institute, a corporation formed under and existing pursuant to the Business Law of this State, which was prosecuted for advertising to practise medicine without being legally authorized to do so. After a legal battle lasting nearly a year the defendant was convicted and sentenced to pay a fine of $150. Mr. Vandiveer had called the attention of the postoffice department to the work of this corporation and the officers of the corporation were prosecuted in the Federal Courts by the United States District-Attorney and Dr. Samuel E. Hyndman, the medical director of the corporation, and William H. Rudolph, President of the Corporation, and one Julius Jellsik, were convicted and were sentenced to imprisonment at Atlanta, and Dr. Hyndman was fined $500. Other instances were cited where the counsel had called the attention of the postoffice department to persons who were using the mails to defraud. The Tompkins Corbin Company, an institution having patented proprietary medicines for the treatment of cystitis, diabetes, and uremic poisoning was also convicted upon evidence obtained by the Counsel of the Society. The Manhattan Medical Association, which offered to the public the services of doctors, dentists, oculists, and opticians at fees varying from ten to twenty-five cents, was summoned to court and finally pleaded guilty. The court suspended sentence in this case because the attorney for the defendant corporation showed that the corporation had completely abandoned the business of treating the general public, and because the certificate of incorporation was legal at the time that the company was incorporated, but became illegal after the passage of the medical practice law passed in 1907. Likewise they had failed to convict the Oppenheimer Institute because it was in operation under a certificate of incorporation issued before the present medical practice act was passed. It was the purpose of the Counsel to compel this institution to obey the provisions of the present law.

Mr. Vandiveer then related some of the facts in con-

nection with the Rheumaticide Company, which was convicted and fined $250, and with the Anthos Company, whose method was to give lectures to Ladies' Aid Societies in churches of various denominations and to obtain the names of the women attending, and then these women were visited by agents of the company and the remedies of the corporation were recommended or prescribed.

Men professing to practice mechanotherapy were among the most persistent violators of the present medical law. Two educational institutions, the Institute of Science at Rochester, N. Y., and the American College of Mechanotherapy at Chicago, Ill., graduated men to whom they gave diplomas with the degree M. T. D., doctor of mechanotherapy. These men offered to cure practically every form of disease by means of manipulation, massage, baths, and herbs. They had banded together and one attorney was now employed to defend the mechanotherapists who were arrested at the instance of the Society. Among this class five men had recently been convicted. Several hypnotists were convicted and also a number of druggists who were found guilty of prescribing over the counter and of selling drugs to procure abortion and to prevent conception. A number of unregistered physicians were found to be practicing medicine; this was especially true of Italians, some of whom were well qualified but had neglected to take the examinations and procure licenses.

Mr. Vandiveer also told of the conviction of a num- of midwives and metaphysicians and related the interesting case of the prosecution of the Christian Scientist, Willis Vernon Cole, who was arrested at the instance of the Police Department and charged with practising medicine without a license, and also the cases of Wentworth Byron Winslow and Julius Benjamin. These cases had been transferred to the Court of General Sessions where they would be conducted by an Assistant District Attorney and not by the counsel of the Society, unless he was especially appointed by the District Attorney to try them. The general defense offered by these men was that the exception in the statute which said that the law should not be construed to apply to the practice of the religious tenets of any faith exempted their acts and permitted them to do as they were doing in the practice of the tenets of the Christian Science Church. The question as to what the tenets of the Christian Science Church were was a difficult one to decide, as Mrs. Eddy's book did not specifically name or include the acts of the Christian Science healers. Closely allied with the Christian Science prosecutions were those of the High Priestess of the cult of Advanced New Thought, who mixed clairvoyancy with dissertations on the principles of Advanced New Thought and with actual rubbing of alcohol on the affected parts and with prescription as to the diet to be followed and colors to be worn in order to calm the nervous system. They had also dealt with the system known as "Chiropractice," the principle of which was the manipulation of the spinal column by pressing with the hand to bring about a proper circulation, thus tending to cure all diseases. In the trial of one of these practitioners it was brought out that he had among his patients many prominent society women.

During the past year at least 300 investigations of complaints had been made by the counsel of the Society. The evidence, while not sufficient to warrant prosecutions, had been obtained and might be of considerable use in the future. The work done by the Society in prosecuting violators of the medical law was generally known to the public and to the Police Department and they had worked in conjunction with many organizations engaged in bettering social conditions in New York City.

Report of the Committee on Legislation.—Dr. E. Eliot Harris, chairman, said there were introduced 3,668 bills in the legislature of 1911, of which number 1,713 were Senate bills and 1,955 were Assembly bills. To these bills there were over 1,000 amendments printed in both houses. The New York Legislative Index Company of Albany furnished the committee with about 200 so-called medical bills.

These so-called medical bills that were killed or died a natural death with the expiration of the legislature, were too numerous to mention even by title. Of those killed there were seven which provided either to regulate, or to inspect, or to supervise, or to establish a commission to investigate animal experimentation. These bills were being each year more carefully framed to hide their true purpose, but were any one of them placed upon the statute book such a law would have the effect of hindering the trained workers in medical research and would militate against the interest of humanity and of individuals and the public health.

MEDICAL ASSOCIATION OF THE GREATER CITY OF NEW YORK.

Stated Meeting, Held November 20, 1911.

The President, Dr. Reynold Webb Wilcox, in the Chair.

A New Sigmoidoscope.—Dr. Anthony Bassler presented this instrument. Among its features are: ease of introduction; tube so marked that the distance up from the rectum, when lesions are met with, can be quickly estimated; advancing rim protected from injuring the mucous membrane; window quickly put on and taken off, without requiring any in or out force to be exerted; tube tightly closed when the window is on, so that air from the bowel cannot come back into the operator's face. The basin-shaped proximal end permits of turning the instrument without the necessity of a handle. The light carrier is held in place by a screw attachment, so that the bulb cannot slip back into the tunnel and cause the darkening of the further end. The air tunnel leading into the lumen is part of the solid instrument, and not of the detachable window. A single ball can be used for the inflation without a special connection therefor.

A Case of Chondrodystrophy.—Dr. George Dow Scott said that, as the cause of this condition was absolutely unknown, the designation "fetal rickets," sometimes applied to it, was an entire misnomer. The pathological process began in fetal life and consisted of a disturbance of the normal ossification of primary cartilage. The flat bones and the vertebræ escaped, while the bones of the extremities suffered most. This patient, a child of 19 months, showed the characteristic short arms and legs, with the skin lying in deep folds and the flesh "cuffed" on itself, in consequence of the shortness of the bones. A depressed, flattened nose, prominent forehead, large, round head, open fontanelle as large as a ten cent piece, and the so-called trident hand completed the picture.

Saratoga Springs—History; Origin; Chemical Constituents; General Therapeutic Action.—Dr. D. C. Moriarta of Saratoga said that, notwithstanding the fact that Saratoga Springs had long enjoyed the reputation of being a great health resort, many persons who had gone there to drink the waters had done so in a desultory manner, and the local medical profession had not given these great natural therapeutic resources the consideration they deserved. In the winter of 1908-9 an organized effort to bring about a change in this condition of affairs was inaugurated by the Saratoga physicians, and to help in this Dr. Comstock and himself decided to imitate the work reported from the European spas, so far as they were able. These springs were all of the saline variety, saturated with carbonic acid gas. The predominating chemical was sodium chloride, with other ingredients in lesser quantities, and according to the predominance of

these chemicals several types of water were recognized: the cathartic, the alkaline, the chalybeate, and the sulphur A remarkable fact concerning these waters was that the quality and quantity of the chemicals contained in them had not fluctuated since their early discovery. The first spring known was the old High Rock, the water of which found its way to the surface, through thirty feet of earth, by the pressure of its own gas. The result of the first drilling was the famous Geyser spring (about 1870), and this bore no relation to the fault in the rock, which for so many years it had been thought necessary to follow if mineral water was to be found. The origin of the springs at Saratoga had been discussed at various times by learned chemists and geologists. To the speaker's mind the most important feature was the origin of the carbonic acid gas. As there was no acid to account for the evolution of this from the decomposition of the carbonates, it must be concluded, he thought, that such decomposition was caused by heat, and also that it occurred in a region remote from the springs, since there was no geological evidence of a high temperature immediately beneath the site of Saratoga. The special character of each spring was probably determined by the particular chemicals existing in the channels through which the carbonated water found its way. The trouble with the Saratoga springs began about fifteen years ago, when commercial industries began collecting the gas from the waters, condensing it, and shipping it for the market. To meet the demands for the gas, deeper pumping was resorted to, and, as the demand continued to increase, larger plants were built and more powerful pumps installed. Finally, deep water gang pumps were set up which pumped, in all, 1,000 gallons a minute, continuously day and night; the gas being collected and the water wasted. Naturally, the level of the water was lowered by this exhaustive pumping, making it a physical impossibility, except in rare instances, for it to flow at the surface as it had done formerly. When this had become known the conclusion was formed by both the laity and the medical profession that the springs at Saratoga had failed. The simple fact, however, was that the water was not allowed to accumulate, as it had formerly done. The solution of the question why the pumping did not affect all the springs alike was to be found in the fact that certain areas were less affected by it, probably because of the impervious walls separating one stratum of earth from another. The water wasted at these gas plants had been repeatedly analyzed, and the chemicals found to exist always in the same relative proportion, though not in the same quantity, as in the original analyses. The few grains difference per gallon in the total salts was no doubt due to the smaller quantity of gas, as, naturally, water 500 feet below the surface would not contain the same amount of gas in solution as water flowing at the surface. Having referred to the prohibiting of the pumping and the creation of the Saratoga State Reservation by act of Legislature, Dr. Moriarat said that, while the entire scheme of the commission appointed by the Governor had not been made public, it had already purchased for the State a number of springs and gas plants. The fact that it was now known positively that the spring waters possessed just the same qualities as formerly should make it possible to reestablish the confidence of the public in the waters and restore Saratoga to her old-time prosperity. In considering the therapeutic value of the waters two essential points were to be borne in mind: (1) that we were dealing with a composite remedy, and (2) that the results would be modified, as in the case of other drugs, by the general state of the patient's health. Since in the analysis of the springs there was no deviation, a definite amount of water always represented a definite amount of the ingredients in solution, and might be estimated and prescribed accordingly. While each type of water depended of necessity on its ingredients for its action, the clinical results would be modified by the quantity of water taken, as well as the hour at which it was taken in relation to food. The cathartic waters had a stimulating effect upon the mucous membrane of the stomach and intestines, dissolving the mucus, increasing the natural secretion, and exciting peristalsis. The alkaline waters had the action of the alkaline salts. They would neutralize free acid, of course, whenever taken; but if used for an acid condition of the stomach they were better taken after food, since, as Bartholow taught, alkalies taken before meals increased the total acids. Brunton and Ringer advocated their administration before meals, believing that they increased the flow of gastric juice and that the carbonic acid present stimulated the mucous membrane and glands of the stomach. The chalybeate waters were of use in anemia, and it seemed that bicarbonate of iron was more readily taken up than iron salts generally. With the genuineness of these waters certified to by the State, there could be no further question as to their therapeutic value. The speaker next described the great natural and added advantages in general of Saratoga as a health resort, and then went on to say that within a short period the local physicians had awakened to the necessity of an individual regime for their patients. They now made a routine practice of taking a complete history before prescribing the waters to drink, the diet, amount of exercise, periods of rest, etc., and the services of an efficient physiological chemist were available for laboratory work. The bathing in the mineral waters would seem to be quite as effective therapeutically at Saratoga as at any foreign spa, but this had never taken on the popular and social side there as abroad because the bathing facilities were limited and lacked the luxury and elegance of the foreign pavilions. The village had, however, in addition to the mineral and sulphur bath houses, the Saratoga Bath House, where the Turkish and Russian and special douche baths were given, and where there was a very large swimming pool. Here there were always trained attendants to give or direct such mechanical therapeutics as might be prescribed for special cases. At the Strong sanatorium there were similar appliances and, besides Russian and Turkish baths, all kinds of hydrotherapy and electrical treatment were given.

Saratoga Springs—Specific Clinical Indications.—Dr. George F. Comstock of Saratoga said that the number of these springs and the manner in which their properties varied enabled the "Kurarzt" to meet many clinical indications, and he could confidently seek therapeutic success here from nature's wholesome forces in the admirable combination of air, exercise, baths, and waters which assisted to so great a degree in increasing the powers of nutrition, and so of resistance, of the human organism. It was with this knowledge in mind and with the hope of furthering such a work that a cure had been established at Saratoga Springs, where the laboratory side had been given the prominence it justly deserved; for it was through the laboratory findings that we best judged the condition of a patient's metabolism and followed the effect of our regime with accuracy. Having quoted from Chittenden and Mendel in regard to the rôle played by the inorganic salts in metabolism, he said that to obtain the best results in using the Saratoga waters it was obvious that no hard and fast rules could be laid down, but it was essential that they should be drunk at the spring itself to get them at the temperature at which they left the earth and in their freshest state; when they were not only more efficacious but more palatable. A proper discrimination should be made in prescribing the waters, as it was only in those cases to which an individual water was adapted, and where this water was properly taken, that we could expect to see the wished-for result. Indiscriminate drinking, and especially mixing, of the waters did much harm, by caus-

ing severe headache, loss of appetite, intestinal irritation with diarrhea, and a general feeling of malaise. It was not possible in the time allotted to refer to all the numerous conditions in which the waters were indicated, and he could only touch upon a few in which especially good results had been obtained. With a certain class of patient, the high-pressure business man, who so often passed on to the later stages of arteriosclerosis and its resulting complications, the "Kurarzt" could work a veritable transformation if he were able to secure a proper cooperation. By means of the changed conditions of living and the active catharsis, diuresis, and diaphoresis obtained by the mineral waters the toxemia of faulty metabolism from which the patient had been suffering was weeded out as it were, roots and all, and a blood-pressure which had hovered around 180 became reduced to 150 or 140, and often even nearer the normal. It was not alone in the early stages of high blood-pressure, however, that relief could be secured by the cure regime. In many instances of long-standing arteriosclerosis, with its concomitant unpleasant symptoms, the same result had been accomplished. In diabetes he had seen so many remarkable improvements, both in early and late cases, that he had come to look upon the Saratoga waters as being of the first importance in the treatment of this disease, in which the alkalinity of the blood was always low from the continued loss of its inorganic constituents. By the use of large quantities of the alkaline waters the alkalinity of the blood was increased and the osmotic properties of the body fluids restored to their normal condition. As high as eight quarts of these waters in 24 hours had sometimes been taken for several days before the desired effect could be secured—an alkaline urine. This once obtained, one could feel assured that with a proper diet a good result would follow. The carbohydrates should not be withdarwn to too great an extent. In fact, in many instances they had to be increased, for it had been found that patients could take even large amounts of carbohydrate, provided only one kind were given. With most, oatmeal was tolerated best, and wheat flour least. The mineral waters, by their direct action on the parts, gave more striking results in the gastrointestinal tract than anywhere else. In chronic gastric catarrh with abundant production of mucus, muscular atony, and diminished reflex irritability of the mucous membrane, the alkaline water, with its carbon dioxide, acted not only as a solvent of the mucus, but also as a direct stimulant to the stomach-wall; causing thus an increase in both motility and secretion. In both hyperchlorhydria and hypochlorhydria, contradictory as the statement might seem, a beneficial effect was produced; in the one by the neutralization of the excessive amount of acid, and by inducing renewed and continued secretion of the gastric juice in the other. Chronic congestion of the liver was frequently successfully treated by the waters and the cure regime, and in commencing disease of the gall-bladder and bile-ducts, before too great inflammatory changes had occurred in their mucous membrane, brilliant results had been obtained. Gallstones having once been formed, all that could be hoped for was the lessening in a measure of the resulting inflammation. In order to overcome chronic constipation it was necessary to prescribe a correct diet and sufficient exercise. Here the saline water was ordered to be taken before breakfast, at its normal temperature, and in sufficient quantity to produce a watery movement. It was a mistake to suppose that these waters were more active when taken hot, as he believed that the cool water excited peristalsis reflexly and energized intestinal action in a way that warm water could not do. In gout and gouty arthritis an increased uric output had been demonstrated, the patients showing a corresponding improvement, while rheumatoid affections were improved by baths, manipulations, and waters. In nephritis the increased elimination caused by the waters gave marked relief, and skin diseases were improved both by the sulphur baths and the saline-alkaline waters. Obesity was well controlled by the same waters and by exercise and diet, and the anemias and chlorosis did well as the result of the tonic environment and the use of such saline waters as contained considerable traces of iron. After speaking of baths and other external adjuvants, Dr. Comstock remarked that in conducting the course of treatment each patient must be considered individually in regard to the nature of his disease, his powers of resistance, and his previous habits. In all cases it was necessary to restrict the diet, but not to the extent often carried out in the cures abroad. He then gave a sketch of the daily program of an average individual who was taking the cure, and in conclusion said that the departing patient was warned not to resume active commercial or social duties too soon; for, though it was not requisite to take an after-cure as was the case with many foreign spas, he should get into harness slowly, continuing the open air life and simple diet until strength and well-being were thoroughly established.

Saratoga and Carlsbad.—Dr. P. Brynberg Porter, the recording secretary, read a letter from Dr. F. Schuman LeClercq of Carlsbad in which he said it was a great satisfaction to him to see that the scientific bodies here were realizing more and more what a treasure was possessed in Saratoga, and what grand possibilities it promised for the future, when America, with its admirable energy and thoroughness, had made up its mind to act. "Under the auspices of your influential association," he wrote, "the American medical world at large will be successfully aroused to the consciousness of the unique advantages which Saratoga has over many—nay, all—of the European spas, by the universality of its applicability and by the chemical variety of the springs which the geological strata of the locality have produced for the benefit of mankind. Since the Carlsbad Cure has been stripped of a lot of superstition and tradition, founded on a hereditary adherence to humoral pathological views, and has now become a more common-sense, individualized application of some crude truths, more or less adroitly handled in accordance with honest principles, there remains little or nothing to be said of the "Carlsbad Kur"; which becomes in every instance a special matter, admitting of no generalization. Therefore, even if European spas should not be discussed at your symposium, such experts and shining lights as you have in your association will, no doubt, successfully elucidate the eminent blessings to be derived from Saratoga, when they direct their searchlight, in the Edisonian spirit and geniality, on the fact that the priceless Rheingold of Saratoga has at last been recovered."

Franzensbad and Its Remedies.—Dr. Bruno Fellner, Jr., of Franzensbad said that the three most prominent watering places of Bohemia had been compared to the members of a body destined to serve the health of suffering humanity: Carlsbad being designated as the stomach, Marienbad as the intestine, and Franzensbad as the heart. Formerly, at Franzensbad, the drinking of the waters was considered the most important feature of the treatment. This was not now the case, though considerable importance was still attached to it. There were a number of springs rich in iron which had long been valued in chlorosis and anemia, as well as other weakened conditions. After seven years' practical experience he could state that more particularly the chlorosis of young girls and the anemia associated with a variety of enfeebled conditions of the female genital organs were very favorably influenced by Franzensbad cures; which, in addition to the water drinking, included hot moor or mud baths. Other springs yielded alkaline waters containing sodium sulphate, sodium carbonate, and free carbonic acid, and the use of

the water from one of these, the Salzquelle, in combination with mud compresses was declared by the well-known clinician Frerich to constitute the ideal treatment for various gastric affections, especially ulcer. The Nathalie spring, containing a fair amount of lithium, was employed in gout and similar conditions. All the springs were very rich in natural carbonic acid, which favored the assimilation of various substances, particularly the salts of iron. According to Frerich, the greatest treasure possessed by Franzensbad was its iron mineral-moor. Whether their action was mechanical, chemical, thermic, or bacteriological, the results met with from the use of the moor baths were marvelous. Pleuritic and peritoneal deposits, exudates of all kinds, especially in the pelvic organs, nodules and deformities in bones and joints (in rheumatic conditions, gout, etc.) were scarcely ever able to resist their absorptive and hyperemic influence. They were the sovereign remedy for all sorts of gynecological affections, and had a special stimulating action upon the ovaries. This might account for the cure of sterility as obtained at Franzensbad; which, though often scoffed at, had nevertheless been proved in a considerable number of cases. The preparation and application of the mud baths had been developed into an exact art. Each bath was prepared individually with the same mineral water which flowed through the moor in nature, and the temperature and duration of the bath were increased very gradually and with scrupulous care, in accordance with the prescription of the physician. The natural carbonic acid baths had been found to diminish the frequency of the pulse, regulate the blood-pressure, and increase the active reaction of the vasomotors, and Dr. Fellner had been able to demonstrate that, under a rising dosage, the heart was first soothed, then exercised, and finally strengthened. Other physical measures, such as gymnastics and massage, were combined with the baths, and special stress was laid upon an individualizing diet. The patients were controlled with all available methods of clinical examination, for which the facilities were ample, and many who had formerly been erroneously condemned to rest in inactivity were permitted to indulge in invigorating sports. The old proverbial ennui of the health resort had been banished by entertainments of all descriptions, and, altogether, Franzensbad could be regarded as possessing the ideal requirements of a "Herzkurort," or center for the treatment of heart affections.

The Treatment of Stomach Disease at Carlsbad and Wiesbaden.—Dr. H. G. Watson said that the treatment at these resorts really began with the ocean voyage and continued until the return of the patient to work and worry. At Carlsbad among the institutions for the "kur" was the Strangers' Hospital, for the exclusive use of non-residents, which accommodated 400 patients. The following affections were much benefited by the treatment at Carlsbad and Wiesbaden: chronic catarrh of the stomach and intestines, hyperacidity, abnormal irritation leading to spasm of the cardia or pylorus, atony and dilatation of the stomach, chronic ulcer of the stomach and duodenum, different forms of dyspepsia due to the liver, gall-bladder, stomach, or intestines, chronic constipation, and chronic diarrhea. Cases of achylia gastrica were treated most satisfactorily at Wiesbaden. The treatment consisted of drinking the waters, taking the proper baths, dieting, exercise, and rest. Precise directions were given by the physician as to the spring one should drink from, the number of glasses, kinds of baths to take and the length of time, the diet, and the hours for rsting, exercise, and sleep. The principal constituents of the Carlsbad water were sodium sulphate, bicarbonate, and chloride and calcium bicarbonate. The temperature of the water in the different springs varied from 95° to 162.5° F. The mode of action upon the stomach and its secretion was complex, but in cases of hyperacidity in connection with ulcer and atony it had been demonstrated that there was a diminution of the hydrochloric secretion up to 50 per cent. as a result of the four weeks' course of the Carlsbad waters. Taken hot, in small doses, the water had proved successful in various cases of diarrhea. The effects of the baths, for which the facilities were profuse in Carlsbad, was secondary in importance, though they no doubt helped toward a cure. The most beneficial in stomach diseases were the hot Sprudel and hot mud baths. The following articles were excluded from the diet while taking the cure: fresh fruits, salads, acids such as vinegar and lime juice, cheese, butter, canned, dried, or smoked fish, nuts, sweets, wine, and all highly seasoned dishes. Wiesbaden was a good place in which to take the cure in the autumn and winter months. All stomach diseases were treated there, but it was best for cases of low acidity and those with rheumatic tendencies. There were twenty-three springs, the principal one being the Kochbrunnen. Its temperature was 144° F., and its chief ingredients sodium chloride and salts of potassium and lithium.

The Relative Merits of the Spa Treatment of Heart Troubles at Bad-Nauheim and in America.—Dr. Louis F. Bishop said that every resort where any particular form of disease was handled had some special kind of treatment which characterized that place, but it was recognized that the elemental treatment at any such place was not the whole cause of the improvement in the patient. At Nauheim the elemental treatment was the carbonated saline bath, and it had gained its reputation, in a great measure, through the use of this bath in conjunction with resistance exercises. Those who had attempted to copy the Nauheim treatment in other parts of the world had taken great pains to copy the chemical composition of the baths, as well as the mode of administration, but had often neglected to try to copy the other elements of the cure. We had to acknowledge that people with circulatory disease who went from America to Nauheim often came back greatly improved, and, as obviously we could not send all our patients of this character to Nauheim, it behooved us to discover how we could imitate the Nauheim cure right here at home. When the Germans spoke of a patient taking a cure they did not mean that the treatment undergone would necessarily lead to the removal of the disease; what they understood by a cure ("Kur") was a course of treatment and a period spent under changed conditions, by which a person who was suffering from, or threatened with, some disease was put in the best possible condition. This conception of the word cure was very important, and we needed to learn it in this country. The American people should be taught that persons generally, and certainly those past middle life, should give up a certain time every year during which they were to be put in the best possible condition. A vacation was supposed to do this, but that was a random sort of thing, and quite frequently people came back from their vacations in worse shape than when they went away, as a result of unsuitable hygiene, dissipations, or various other causes. In Europe they combined a vacation with a cure, and obtained great benefit, and the fact that this was generally done had led to the great development of cure resorts. Dr. Bishop then proceeded to describe some of the characteristics of the Nauheim cure. The cooking, he said, was plain (vegetables cooked in water and no made-over dishes), and the meals were served very deliberately; so that the patient ate slowly and carefully. A band was generally playing in the garden of the hotel, where the meals were served in good weather, and the meal hour was thus rendered a pleasant diversion. The place was so attractive that the temptation to be out of doors was great. When persons first came to Nauheim they were inclined to sleep a good deal, partly on account of a certain quality in the air and partly because coffee deprived of its caffeine was

always served. The organization of the place was so complete that all disagreeable things were kept out of sight, and one element in the success of the cure was the hopefulness and general spirit of optimism prevailing. The maintenance of a proper moral atmosphere was very important in the handling of cases of heart disease. When the patient first came to Nauheim all drugs, stimulants, and tobacco were removed from him, and it was the practice to restore such only when in the patient's treatment they were actually needed. The baths consisted essentially of a strong brine bath, with a considerable amount of calcium chloride and a certain amount of carbonic acid gas. In imitating these in America persons were apt to add more carbonic acid gas than was in the Nauheim baths and to forget all about the salt. It took a good many pounds of salt to make a bath-tub-full of water of the same strength as the natural bath at Nauheim. A man who had learned the ultimate principles of the treatment of heart disease, and had sufficient strength of mind, could get just as good results in New York as were met with at Nauheim; but, on account of the absence of the natural baths, of the peculiar air, of the diet, and of the proper kind of exercise, as well as of the atmosphere of hopefulness, it would be essential that he should exercise an iron control over his patient. The Nauheim treatment had been imitated in a considerable number of places in America, with varying degrees of success. Everything depended on the physician, and whether he could control the conditions. The trouble with health resorts in this country was that they were often essentially money-making institutions, while the medical control was not absolute, or else so many kinds of affection were treated that the heart patients could not receive the special different attention they required. Often the baths alone, without the requisite regimen, were not worth taking, and often both the baths and exercises were stronger than was wise. The speaker thought we ought to have a place in America that was not too fashionable and not too much devoted to money-making, which should be under the direction of a man especially qualified for this kind of work, and not too far from New York, so that the patient could be more or less under the control of his own physician. On the whole, however, it was better for the physician to undertake the treatment without attempting to get the assistance of any particular place, and if he would bear in mind that a cure at Nauheim meant a period spent under conditions designed to contribute to the well-being of the patient, that the word did not mean the magic removal of disease, and that change of scene, diet, exercise, and the withdrawal of all depressing influences were just as essential a part of the treatment as the baths, he could carry out the spirit of the Nauheim treatment with his patients.

Some European Spas—A Peep Behind the Scenes.—Dr. Heinrich Stern criticized certain of the health resorts of Germany, and the commercialism prevailing there, with no little severity. He said that almost within his own recollection the medical powers had caused Nauheim to change its skin three times. Until about 1870 its waters were exploited as a sure cure for tabetic degeneration; from then until the early nineties it was mainly rheumatics who swelled the coffers of the Nauheimers, and ever since it had been the cardiopaths, real and imaginary. The water of the Karlsbrunnen, however, had remained precisely the same, and the amount of its carbon dioxide was decidedly less than that of Soolsprudel in Kissingen, the Soolbrunnen in Soden, the Elizabethbrunnen in Homburg, and the Salzquelle in Pyrmont, and less than half that of the warm Soolsprudel in Soden. This was not certainly an impressive showing when it was remembered that carbon dioxide was the main asset of contemporaneous Nauheim. In the beginning of its cardiocurative era the place had no other method than that in vogue in dozens of other German health resorts, the Oertel terrain cure. The resistance movements came as an afterthought, and thus on the flimsy basis of carbon dioxide and Swedish gymnastics the reputation of Nauheim was founded. Granted, even, that there ensued a transitory feeling after a Nauheim bath or exercise, would any thinking physician really maintain that lasting benefit to the genuine cardiopath would result from a course of the Nauheim treatment? It could be positively asserted that the Nauheim physicians entertained no such delusion. But few foreigners traveled directly to a German watering-place. They were mostly directed by their home physicians to certain well-known consultants in various cities, especially university towns. These gentlemen did the final apportioning. They might send the patient to this or that resort, but he would always land in the office of a secret co-partner of the great professor. The division of fees between certain "Badeärzte" and the referring consultants was an open secrét; it prevailed at all German health resorts where there were more than half a dozen practitioners. At Wiesbaden the local profession counted some of the most illustrious German physicians among its members, and the practitioner there depended much less upon a business connection with the medical authorities than did his confrère in smaller health resorts. Wiesbaden, however, abounded in mucous membrane specialists of every type, and, though some of them prescribed the Kochbrunnen water, the real benefit to the patient resulted from treatment other than balneological. Some very good work concerning the pathology and treatment of gout had been done in Wiesbaden, but the speaker said he had never been able to fathom the causative connection between the mild sodium chloride spring and the cure of this affection. Aix-la-Chapelle (Aachen) was far-famed for its method of treating syphilis, but Wiesbaden had stolen the thunder of the Aacheners by employing their methods, and its syphilitic clientèle was now actually larger than that of Aachen. Why should a man sneak to Aachen for treatment (which fact alone stamped him as a syphilitic) when he could pose in Wiesbaden as one of the 50,000 sufferers from mucous membrane disease who annually gathered there? As far as the cure-tax was concerned, Wiesbaden was more liberal than the smaller spas, though the custom that the townspeople paid 10 per cent. less than the cure guests for everything they bought also prevailed there. The reputation enjoyed by Schwalbach was due to its Stahlbrunnen, with its iron bicarbonate and carbon dioxide, but the local conditions doubtless contributed not a little to the well-being of many of that species of English hothouse females who frequented this tranquil resort. It was entirely natural that a certain proportion of cases of uterine disorder depending upon anemia should be benefited by a course of treatment there; but it was the combination of change of surroundings, rest, bracing air, regulation of diet, and hydrotherapeutic and balneological measures in general which brought about the improvement. The iron water alone would probably not accomplish much. As to the alleged efficacy of the treatment both at Schwalbach and Franzensbad in the cure of sterility, Dr. Stern was rather skeptical. Homburg was the most fashionable, as well as the most expensive, of German spas. It had for many years been a resort of the English aristocracy, and the German public in general knew very little about it. Really sick people rarely went to Homburg, as the place was not sufficiently a freak of nature to attract real live patients without so-called scientific work on the part of its physicians. These were quite contented, and they had not created a specific system of treatment because there was no need of such. Though the practice of medicine was of secondary importance there, it was a pleasure and recreation to practise at Homburg. The duties were light, the fees high, the chances great—the chance to become a

duke's private physician or to marry an English heiress. Health resorts might serve a good purpose, but the fake sanatorium, with its eccentric dietary and pseudo-religious atmosphere, had no place in the honest practice of medicine. It was such, and the railroad companies exploiting every tepid spring along their lines as a cure-all, that were preventing a natural development of spas like our own Saratoga.

Dr. George Meyers said the success of spa treatment was in reality due to the change of scene, air, habits, and regimen, and it seemed to him that the result would be just the same if the baths and the mineral water drinking were omitted.

Dr. L. L. Seaman said that in the library of the Academy of Medicine were two volumes published by his grandfather, Dr. Valentine Seaman, respectively in 1793 and 1809, containing elaborate analyses of the Saratoga waters, and it certainly seemed remarkable that analyses made at this early date were so accurate and so nearly identical with those of the present day. A familiarity with the waters of many of the springs abroad led him to believe that at Saratoga and in the Yellowstone Park we had waters which possessed remedial properties equal, if not superior, to those of any European spa, and it was a matter for congratulation that both our State and National governments had at last awakened to a realization of the enormous value of these assets.

Dr. T. E. Satterthwait said that, notwithstanding all that might be said against the foreign spas, he believed it to be true that these resorts afforded unusual opportunities for the special study of disease, because at each were to be found a large number of cases of one particular class. At Franzensbad there was a physiological laboratory belonging to the town and facilities were offered the physician for availing himself of everything which would throw light on a case scientifically. Something of this kind, he thought, was what was most needed at Saratoga.

Dr. Moriarta said he could not agree with Dr. Stern and Dr. Meyers. It was scarcely reasonable, he thought, to assert that mineral waters with a definite amount of active medicinal agents in their composition did not have any effect. In these waters we were dealing with a composite remedy, and one which must be used with discrimination.

Dr. Comstock said he could not believe that patients who merely took a rest, with change of scene, but without the benefit of mineral waters, would do just as well as those who had such additional benefit. Thus, he had seen a good many Cubans in poor health who had come first to New York and then gone to the mountains without getting any better. For the most part they were jaundiced, had disordered livers, and were suffering from anemia; and invariably, unless some organic trouble was present, they were immensely benefited in every way by a course of treatment at Saratoga. It seemed evident, therefore, that the improvement was due more to the waters than to simple change of environment and mode of life. These had their effect, however and he agreed with Dr. Bishop that the general air of hopefulness which was met with at health resorts constituted, by its moral effect, an important element in the benefit to the patient.

Colloidal Nitrogen in the Urine in Cancer.—Maucini, employing Salkowski's method of determining the colloidal nitrogen in the urine, found that when the kidneys are healthy the excretion of colloidal nitrogen is increased by all processes that increase the amount of colloidal nitrogen in the blood and lymph, namely, exudates and transudates, pneumonia, pleurisy, circulatory failure, and inflammatory and suppurative processes. The increase associated with carcinoma is attributed to metabolic changes and to autolysis of the tumor.—*Deutsches Archiv für klinische Medizin.*

Pathological Society of Philadelphia.

At a stated meeting held November 23, Dr. H. B. Allyn exhibited a specimen of "Primary Cancer of the Gall-bladder with Secondary Cancer of the Liver." Dr. M. B. Hartzell demonstrated "A Convenient and Effective Method of Paraffin Imbedding without a Thermostat." The device comprises a so-called thermos bottle partially filled with hot water, and over which is placed a test-tube containing the paraffin, which, when liquefied, impregnates the bit of tissue removed from strong alcohol. With the test-tube is connected a water vacuum-producing mechanism for the abstraction of the chloroform vapor, a flask being interposed between the two to receive any overflow. By the use of this device tissue can be imbedded in a half-hour without risk of in any way injuring the tissue. It has proved most satisfactory in an experience of more than two years. Dr. Percival Nicholson made "A Demonstration of a New Sphygmomanometer." The instrument is small enough to fit into a 15-inch bag and it weighs about two pounds. It consists of a U-shaped tube through which flows a column of mercury and which is secured to the lid of the containing box. It is ready for use when the lid is deflected upward at a right angle. The escape of the contained mercury is prevented by means of a stop-cock, which must be shut off before the lid can be closed. The escape of air is prevented by means of a needle valve, and an additional cock is provided to preclude such escape. The cuff is lined with felt so that it may fit snugly and not slip when applied over the covering of the arm. The air is introduced by means of a small hand pump. Dr. Karl F. Meyer made a demonstration of the "Serodiagnosis of Glanders," and pointed out the practical utility of this procedure, especially in veterinary medicine. Dr. S. S. Woody presented a communication entitled "The Epidemiology of Measles." He pointed out that the disease prevails in practically all parts of the world, and that its incidence is largely in children, adults escaping principally because of the immunity conferred by an attack in early life. It occurs at all seasons, but is observed most frequently in the winter because of the confinement of children indoors and the greater opportunity for conveyance. It is transmitted by more or less immediate contact. It seems probable that the infection resides in the discharges from the mucous membranes and little if at all in the scales. Dr. John F. Anderson, Director of the Hygienic Laboratory of the U. S. Public Health and Marine Hospital Service, read by invitation, a paper entitled "Experimental Measles." He cited observations showing that the disease could be conveyed from man to monkeys by means of the blood and of the discharges from the nose and pharynx, but the infectivity gradually disappears after the fourth day of the disease. Dr. John A. Kolmer read a paper entitled "Streptococcous Antibodies with Special Reference to Complement-fixation." His investigations were directed in part to determine whether the streptococcus bears any etiological relation to scarlet fever, and also the utility of a streptococcus vaccine in the treatment of this disease. He reached the conclusion that the streptococcus is not specific for scarlet fever, and that vaccine treatment might be useful for complications but not for the disease itself.

Cardiac Tumor Causing Heart-Block.—Armstrong and Mönckeberg demonstrated in a case of heart-block in a five-year-old child the presence of a lymphangioendothelioma at the site of the bundle of His.—*Deutsches Archiv für klinische Medizin.*

Syphilitic Cardiovascular Disease.—Jakobäus believes that this is more common than is generally realized. Aortic insufficiency particularly is due not only to direct syphilitic processes, but also to indirect arteriosclerotic changes.—*Deutsches Archiv für klinische Medizin.*

Medicolegal Notes.

Physician's Book of Accounts Held Competent Evidence of Services Rendered.—A claim was made against an estate for services rendered and medicines furnished to the decedent by the claimant as a physician, and contested by the administrator, whose chief objection was that the physician's book of accounts was incompetent as evidence against the estate because of the provisions of section 829 of the New York Code of Civil Procedure, forbidding a party to testify at the hearing on the merits of a special proceeding against the personal representative of the decedent as to personal transactions between the witness and the decedent. The rendering of the services was abundantly proved by the claimant's book of accounts, if that book was properly received as evidence. The book was produced by the claimant and identified by him as his book of accounts. He testified that he made the entries in it, and that he so made them at the time the transactions referred to occurred, and that he kept no clerk. He then proved by others that some of the services charged for were rendered, that some of the medicines charged for were delivered, that the amounts charged were reasonable, and that he kept correct books, the latter fact being shown by the testimony of several persons who had settled with him from the book during the period covered by the account in question, that their accounts upon the books were shown to them, and that they found them correct. In allowing the claim the court distinguished the case from that of Davis vs. Seaman, 64 Hun. 572, where the only evidence that the claimant kept correct books was his own testimony, given under objection and exception. He merely produced his own record of his dealings with the decedent and then swore that the record was correct. In the present case the correctness of the claimant's book of accounts was proved by the testimony of third persons. The book itself was not therefore incompetent evidence merely because of the fact that the entries in it were made by the claimant himself. Any other rule would render it impossible in the majority of cases to establish a claim against an estate, where the claim consists of many items of goods and services rendered. In re Runions, 128 N. Y., Supp. 1030.

"Healer" Without Drugs Practises Medicine Within Meaning of Statute—Power of States to Control Practice.—On appeal from a conviction for practising medicine without a license it appeared that the defendant kept a furnished office for healing the sick and the signs on his windows read, "Professor Smith, Healer." He claimed his treatment was a natural one—a gift from the Almighty; claimed to restore people to health; said he could cure any disease medical men could, and many they could not; could cure diarrhea and stomach, spinal, nervous, and throat troubles, and pneumonia; mentioned several cases of pneumonia he had recently cured that doctors had given up; said he diagnosed his cases and treated them without medicine. He testified that he belonged to the church of "The Divine Scientific Healing Mission," a corporation; that he charged some of his patients and some not; that he could not tell whether they had gout, smallpox, or rheumatism, but could and did treat and cure them. The Colorado statute (Rev. St. 1908, §6069), defines the "practice of medicine as the holding onesself out to the public as engaged in the diagnosis and treatment of human diseases, or the prescription of any treatment for the relief or cure of any physical or mental ailment with intent to receive any compensation, or the maintenance of any office for the reception, examination, or treatment of any one suffering from any disease, or attaching any word or abbreviation to one's name indicating that he is engaged in the treatment or diagnosis of diseases. The act provides that nothing therein shall prohibit the practice of religious tenets or the general belief of any church, whatsoever, not prescribing medicine. It was held that the accused was "practising medicine" within the statute. The defendant was engaged in a business venture, not a religious exercise. The provision of the statute did not authorize one under the cover of religion or a religious exercise to go into healing commercially for hire, using prayer as the curative agency or treatment. The Legislature under the police power of the State could create the State Board of Medical Examiners and fix its powers and duties. The police power of the State relates to the preservation and promotion of the health, safety, and morals of the people. The law is settled that the Legislature ay control the practice of medicine, and define what constitutes such practice.—Smith v. People, Colorado Supreme Court, 117 Pac. 612.

Hypothetical Question as to Insanity.—In a criminal case where the accused's mental capacity is in issue it is improper for the prosecution to state to a medical expert an isolated instance given as a reason by witnesses for the defense for their opinion as to the accused's insanity and ask him if that was an evidence of insanity and so on, one by one, through the category of separate and detached occurrences mentioned by the witnesses for the defense. On the other hand, the hypothetical question should be germane to the matter in hand, and not clouded with references to other matters which, though relating to the crime, do not relate to the question of the accused's insanity. State v. Garrison, Oregon Supreme Court, 117 Pac. 657.

Statute Requiring from Physicians Certificate Containing Certain Facts as to Births Held Unconstitutional.—Sections 14, 17, and 21 of "An act to establish a bureau of vital statistics and to provide for the prompt and permanent registration of all births and deaths occurring within the State of Ohio," so far as they relate to a physician or midwife, in attendance upon a case of confinement, have been held by the Ohio Supreme Court to be unconstitutional and void because they were enacted by an unnecessary, unreasonable, and arbitrary exercise of the police power of the State. The statute imposes upon the physician or midwife the duty of investigating and certifying as to certain facts which would not necessarily or naturally come within the knowledge of the attendant physician or midwife, viz., whether the birth was legitimate or illegitimate, and, except in case of illegitimacy, the full name, residence, color or race, birthplace, age, and occupation of the father; also the maiden name in full, residence, color or race, birthplace, age, and occupation of the mother; likewise the number of this child of the mother, and the number of living children of the mother. This information was required to be supplied without compensation. Without deciding the point, the court doubted whether statutes imposing the duty of making such report or certificate were not unconstitutional because they did not provide for compensation to physicians.—State v. Boone, 95 N. E. 924.

Malpractice—Evidence—Letter That Medical Society Defended Its Members.—After suit brought by a patient against his physician for malpractice the defendant wrote a letter to the plaintiff, stating ,in substance, that the medical society of the State defends its members in actions for alleged malpractice. This letter was offered in evidence by the plaintiff and received by the trial court over the defendant's objection and exception. The re-examination with reference to the letter developed the fact that by reason of membership in the society the member was entitled to be defended by the attorney of the society in such actions, and to that extent the defendant was insured or indemnified. On appeal it was held that the letter was not evidence upon any subject before the jury and it could only tend to prejudice the defendant's case by making the jury believe that the medical society in some way must bear a part of the burden of the defense. Perhaps the jury reasoned that if the defense cost the defendant nothing its verdict against him would not be a very serious burden.

The appellate court thought that the familiar rule in negligence cases excluding evidence that the defendant is insured against liability applied in principle to this case. The letter could not be said to be an admission of the defendant's guilt, as the suit was already pending, but it was an unwise attempt by the defendant to frighten the plaintiff from further prosecuting the case, not by a false statement, but by a statement which, as a matter of fact, rested upon a substantial basis. Perhaps standing alone the erroneous ruling might not call for a reversal, but the case was reversed on another point (see next note).—Terier v. Dare, New York Appellate Division, 131 N. Y. Supp. 51.

Opinion Evidence—Answer—Based on Sufficient Data.—In a personal injury action the plaintiff's right elbow was injured by a dress suit case thrown from a rack on the opposite side of the railroad car in which she was traveling. A physician was asked what in his opinion would be the natural result of an injury to the elbow, such as the plaintiff had received, with respect to synovitis, swelling, inflammation, blood poison, stiffness. It was held that the answer, which was as restricted as the question was not objectionable, although, on cross-examination the physician admitted that the answer was based upon the fact that there was a fracture involving the joint and an injury to the ulna nerve; that those two elements do not always produce the same results; that you have to consider the treatment in order to determine the probability of recovery of a fractured arm, and that he did not take that into account in his answer.—Parker vs. Boston & M. R. R., Vermont Supreme Court, 79 Atl. 865.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ended December 16, 1911:

	Cases	Deaths
Tuberculosis Pulmonalis	465	152
Diphtheria	244	14
Measles	406	11
Scarlet Fever	226	9
Smallpox	2	—
Varicella	225	—
Typhoid Fever	105	13
Whooping Cough	46	6
Cerebrospinal Meningitis	3	2
Malarial Fever	—	—
Totals	1,722	207

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended December 15, 1911:

Places	Date	Cases	Deaths
CHOLERA			
Bulgaria: Varna	Oct. 18	1	..
On s. s. *Boris* from Asia Minor.			
Dutch East Indies	July 17–Aug. 22	127	90
Bulletin Quarantenaire d'Egypte, Nov. 16, 1911.			
Java	Oct. 22–28	9	2
France: Marseilles	Oct. 1–31	..	13
India: Calcutta	Oct. 15–21	..	32
Madras	Oct. 29–Nov. 4	90	70
Italy		..	..
Total, Nov. 5 to 11: Cases 112, deaths 59.

THE QUANTITATIVE ANALYSIS OF HUMAN AND OF COWS' MILK.*

BY ARTHUR V. MEIGS, M.D.,

AND

HOWARD L. MARSH, B.S.,

PHILADELPHIA.

WE have undertaken the quantitative analysis of human milk for the purpose of proving the accuracy or inaccuracy of the analyses published by Arthur V. Meigs† in a paper on Milk Analysis in 1882, and in various subsequent publications, and of cows' milk because of its great importance as a food and because it was impossible not to use it for various experiments, as it is always so easy to obtain. In the paper mentioned it was asserted "that human milk never contains more than from seven-tenths of one, to one and a half per cent. of casein." At that time the term casein was used to designate what is now named the protein of milk. The conclusion that human milk contains only a small amount of protein, much less than had previously been supposed, was commonly accepted as a fact by physicians and the artificial foods recommended for infants have almost all since that time been based upon the estimate that the proper amount of protein for the newborn human infant is about one per cent. Chemists have seemed indifferent upon the subject, and although Meigs has a number of times asked for the confirmation or refutation of the important conclusion in the twenty-nine years that have elapsed since the publication of the original paper, no one has made any investigation with a view to answering the question. Analyses have been published, and continue to be published, by chemists of repute in which the protein of human milk is estimated to be as high as three and even four per cent. It is quite unreasonable to accept as correct analyses that rate the protein as high as three or four per cent., and at the same time to accept the conclusion of Meigs that human milk never contains more than about one per cent. of protein. For many years past, however, physicians have failed to perceive that the two statements are contradictory, and that if the one is correct the other is not. Most analyses have been made by determining the nitrogen by the Kjeldahl method and multiplying by a factor to ascertain the amount of protein, and the copper reduction method (Fehling's) to ascertain the amount of lactose. In many analyses direct determinations have not been made of both the protein and the lactose, but only of one of them, and the other has been estimated by difference. The reason why the determination by difference of one of the ingredients of a complex and unstable organic fluid like milk is unreliable and unscientific has been repeatedly shown by Meigs. No analysis either of human or cows' milk has heretofore been made in which the various constituents were determined gravimetrically—each one isolated from a single sample and weighed separately and the separate weights when added together shown to be equal to the weight of the original sample.

After waiting so many years, and as no one else has undertaken to solve the question at issue, we have been enabled to make an arrangement to carry out an extended study of the subject from the standpoint of pure chemistry. During the past two years we have pursued our investigations, and the junior author has devoted his entire time to the laboratory work. Dr. John Marshall, Professor of Chemistry in the University of Pennsylvania, has given us the use of his laboratory, and the work has been carried on under his supervision, and we have been guided by his advice. During the first year the work was supervised by Dr. William H. Welker, then demonstrator of physiological chemistry under Professor Marshall. While the investigation was being directed by Dr. Welker, it was carried to a point that it became evident that in human milk especially, and in cows' milk to a less extent, there exists a nitrogenous constituent which is not coagulable. This nitrogenous constituent does not react to any of the ordinary tests for protein.

It would have been impossible for us to have carried out the analyses of human milk, which necessitated the use of large quantities, but for the kindness of Professor B. C. Hirst, who placed at our disposal the facilities of the maternity department of the hospital of the University of Pennsylvania. Further, we are indebted to Miss Marion E. Smith, Superintendent of the Hospital, and to her assistants who have obtained from the lying-in women as much human milk as we have required as it has been wanted.

It is important that it should be understood at the outset that in the present state of chemistry it is impossible quantitatively to analyze an organic material like milk and to attain the accuracy of conclusion that can be had when inorganic substances are in question. It is not unreasonable to think that this will always be the case, for the component parts of milk are of composite structure instead of being simple like inorganic elements, and therefore they are liable to undergo change in the course of the manipulations of analysis. This quality makes them to a certain extent elusive. Although such accuracy as is demanded in inorganic analysis is unattainable in milk analysis, on the other hand the fat, protein and lactose of milk are such distinctive substances that it is possible to analyze milk so accurately as to obtain results in all essential features correct.

*Read at a meeting of the College of Physicians of Philadelphia, November 1, 1911.

†"Milk Analysis," by Arthur V. Meigs. Transactions Philadelphia County Medical Society, February 22, 1882, and Philadelphia Medical Times, July 1, 1882.

The percentage of water was determined by the difference between the percentage of total solids and 100 parts by weight of the milk.

The total solids were determined by weighing 5 c.c. of milk in a weighed platinum dish and evaporating to dryness on a water bath. The contents of the dish were then desiccated to constant weight over sulphuric acid.

The ash was determined by slowly igniting the total solids contained in the above mentioned weighed platinum dish. To obtain the best results the platinum dish should at no time be heated to more than a dull red glow. Sufficient heat to produce a dull red glow should be used only during the last few seconds of the ignition. A white ash was produced after about twelve hours' heating.

The determinations of the fat, protein, lactose and extractives were all made from one sample of milk; 10 c.c. of the milk were accurately weighed into a 100-c.c. glass-stoppered cylinder, and to this were added 20 c.c. of distilled water and 20 c.c. of ethyl ether, and the mixture was shaken for five minutes. Then 20 c.c. of 95 per cent. alcohol were added and this mixture was agitated for five minutes. After the cylinder had been allowed to stand a few minutes two layers separated. The upper layer consisted of an ethereal solution of all the fat, a small amount of lactose and an infinitesimal amount of nitrogenous substance which was soluble in alcohol but insoluble in water and in ether alone.

The lower layer contained all of the other solid constituents of the milk.

The upper layer was removed into a weighed glass dish by means of a pipette, care being taken not to take any of the lower layer; 5 c.c. of ether were added to the contents of the cylinder in such a way as to wash down the sides as well as practicable, and this was then drawn off with a pipette and discharged into the same glass dish. The washing in this manner was repeated five times to remove all the fat. The contents of the dish were then evaporated to dryness on a water bath and desiccated to constant weight over sulphuric acid. This water-free fat was treated with sufficient dry ether to dissolve it and the solution was filtered into a small weighed beaker. After thoroughly washing the filter with dry ether the washings were added to the filtrate in the weighed beaker and the solution was evaporated and desiccated over sulphuric acid to constant weight. The residue in the beaker consisted of all the fat originally contained in the milk. The residue insoluble in ether remaining on the filter which consisted of a very small amount of lactose (varying between 0.05 and 0.20 per cent. of the milk) and an infinitesimal amount of nitrogenous extractives, was treated with hot water, which dissolved the lactose, leaving the nitrogenous extractive on the filter. This hot water solution of lactose was added to the lower layer of milk liquid from which the protein had been removed and which contained all of the lactose except that small amount just mentioned.

The remaining portion of the contents of the cylinder, *i. e.* the lower layer, was transferred to a 200-c.c. beaker and evaporated on a water bath to a volume of about 10 c.c.; 100 c.c. of 95 per cent. alcohol were then added, to bring the mixture to a content of 86 per cent. of alcohol, in order to precipitate the protein. This was allowed to stand five minutes before filtering. If allowed to stand longer than twenty minutes there is likelihood of the lactose separating by crystallization. It was then filtered through a weighed alundum porous crucible by means of a suction pump and washed with one liter of boiling 86 per cent. alcohol and subsequently with 500 c.c. of ether. As soon as the protein had been transferred to the crucible all the lumps of protein were very carefully and gently pulverized with a glass rod.

The contents of the crucible were dried at 110° C. and desiccated to constant weight over sulphuric acid. The ash content of the protein was determined by slowly igniting the contents of the crucible. The loss of weight due to the incineration represented the amount of protein.

The clear filtrate and washings from the above precipitate, to which had been added the solution in hot water of the residue derived from the ethereal solution of the fat from the original milk, was evaporated on a water bath to a small volume and transferred to a weighed platinum dish and evaporated to dryness on a water bath and desiccated to constant weight over sulphuric acid. The residue in the dish was then slowly ignited and weighed in order to determine the amount of ash. The loss in weight due to the material burned represented the amount of the lactose and extractives.

The lactose of the milk was determined by Fehling's method. The method was carried out as follows: 25 c.c. of cow's milk, or 15 c.c. in the case of human milk, or the amount of residue containing all of the lactose of the milk together with the extractives secured from 10 c.c. of milk were diluted to 400 c.c. in a 500 c.c. graduated flask, 15 c.c. of N/5 sodium hydroxide, and 10 c.c. of cupric sulphate of the strength used in a Fehling's solution were added and the volume of the liquid in the flask was diluted to 500 c.c. with water.

After this mixture had been well shaken it was filtered through a dry filter into a dry flask; 100 c.c. of this solution were added to 50 c.c. of hot Fehling's solution and the mixture was boiled for six minutes. It was then quickly filtered through an alundum crucible and washed with about 600 c.c. of boiling water. The resulting cuprous oxide in the crucible was dissolved with nitric acid and the solution poured into the beaker which had been used in the reduction. The crucible was then thoroughly washed by passing hot water through it and this wash water was added to the nitric acid solution which had been poured from the crucible. This nitric acid solution of the cuprous oxide was evaporated on a water bath until free from nitric acid. It was then dissolved with acetic acid and water, 8 grams of zinc acetate were added to the solution, and the liquid was transferred to a small glass stoppered bottle. Four grams of potassium iodide were added and the solution titrated against N/10 sodium thiosulphate with starch as an indicator.

The amount of lactose corresponding to the amount of copper found was ascertained by referring to a table given in Bulletin No. 107 (revised) of the U. S. Department of Agriculture, Bureau of Chemistry.

The amount of extractives in the milk was the difference between the lactose plus extractives and the lactose as determined by Fehling's method.

The method of Meigs for the extraction of fat from milk gave the same results as were obtained by the Soxhlet method. It has no effect upon the other constituents of the milk and is decidedly more rapid and simpler in execution than the Soxhlet method.

The protein precipitate produced in the fat extracted milk when alcohol was added so that the

mixture contained 86 per cent. of alcohol was all the coagulable protein of the milk. It was of high purity as it contained only a trace of lactose and extractives. The proteins of the cow's milk and of human milk contained respectively 14.5043 per cent. and 13.1110 per cent. of nitrogen corresponding to the factors 6.89 and 7.62. In calculating these nitrogen determinations the ash was in every case subtracted. The protein precipitate from cow's milk contained the larger portion of the ash of the milk, whereas the protein from human milk contained the smaller portion of the ash.

In this method of analysis we may for convenience term the fat the first fraction, the coagulable protein precipitate the second fraction, and the remaining liquid the third fraction. This third and last fraction of the milk contained all but a very slight quantity of the lactose, a portion of the inorganic salts and some other material of unknown composition, the presence of which chemists have recognized for many years past and have indefinitely named extractives.

Notwithstanding the use of all solvents known to us we have failed in our attempts to quantitatively separate all of the extractives from the lactose. Our best effort succeeded in separating only about one-half of the extractives from the mixture of lactose and extractives, and this portion of extractives contained only a very slight part of the nitrogen which remained in the unextracted portion.

A part of the extractives, however, could be removed by evaporating the third fraction of the milk to a volume of approximately 1.5 c.c. and adding about 50 c.c. of methyl alcohol. At this stage difficulty was encountered in getting the solid residue derived from the 1.5 c.c. of evaporated liquid to completely dissolve in methyl alcohol. The volume to which the third fraction must be evaporated depends upon the amount of lactose present. At too great a concentration the lactose will not go into solution in methyl alcohol, and at too great a dilution the extractives will not go into solution in methyl alcohol, and the lactose will not be completely precipitated when the ether is added. If unable to secure a perfect methyl alcohol solution of the lactose at the first attempt one should concentrate and try again with different volumes.

This methyl alcohol solution was poured into 500 c.c of dry ether contained in a glass-stoppered cylinder and violently shaken for five minutes. All the lactose and most of the nitrogen and extractives separated in large flocculi. The mixture was allowed to stand twelve hours and was then filtered through a dry filter. By evaporating the filtrate a small portion of the extractives was secured. The extractive matter thus obtained was insoluble in water but readily soluble in ethyl alcohol, chloroform, and ether. By slow evaporation from an absolute alcohol solution a very small amount of minute, yellow crystals having a sharp melting point of 115° C. was obtained. The crystals, when observed under the microscope, had the appearance of double wedges.

What advance can we claim to have made? Our method is an advance upon previous analyses because after taking one sample of milk to determine the water, total solids and ash in the usual way, we then from one other sample of the same milk take out first the fat and then the protein and weigh them, each one by itself. Afterwards what remains is dried and weighed; there is, therefore, no chance for loss. This residue contains the lactose, with some salts and a material which contains nitrogen. The nitrogenous material we have been unable to isolate, and of its nature we know little, except that it has solubilities similar to those of lactose. Whether it is in combination with the lactose, or if it simply remains with the lactose because its solubilities are similar we do not know. All that it has been possible to do has been to test the residue by Fehling's method, the best now known, to ascertain the amount of lactose present, and to ascertain the amount of nitrogen by the Kjeldahl method.

By the methods described above the following results were obtained:

	Cow's Milk. Per Cent.		Human Milk. Per Cent.	
Water	88.279		87.569	
Fat	3.032		3.087	
Protein	2.942		1.481	
Lactose	4.482	5.085	6.574	7.574
Extractives	0.603		1.000	
Ash	0.733		0.252	
Total	100.071		99.963	
Experimental Error	0.071		0.037	
	100.000		100.000	

The methods of analysis heretofore ordinarily used have all been more or less indirect. The determinations of water, total solids, fat and inorganic material can be said to be certainly correct except that the amount of salts is underestimated because incineration must cause some change and loss, but this is probably a small error. The lactose and protein and the material of unknown nature, whose presence is acknowledged because of the universal use of the term extractives to describe it, have all been determined indirectly. In many published analyses only the lactose or the protein has been determined and the other one calculated by difference. The protein is generally estimated by the Kjeldahl method for the determination of nitrogen. As far as the determination of the nitrogen is concerned it is accurate, but as there is always nitrogen present in the extractives, there is no way of finding out for certain what factor should be used to multiply the nitrogen amount in order to ascertain the quantity of protein. Fehling's test for lactose cannot be said to yield results which are certainly reliable when the solution of lactose contains other substances which might increase or diminish the copper reduction, and this is always the case in milk analysis. The truth about it, therefore, should be acknowledged that it is the best test for lactose at present known to science, but that the results obtained from its employment in any new field are to some extent uncertain. Some idea of the difficulty of dealing with lactose and of testing it may be had from the statement that we have never succeeded in obtaining a sample of absolutely nitrogen-free lactose. The best that can be purchased always contains a small amount of nitrogen, and even Merck's lactose, after having been dissolved and recrystallized five or six times, still contained a minute amount of nitrogen. By our method the fat is more easily and accurately obtained than by any other. The protein also is better separated. No reagents except volatile fluids—ether, alcohol and water—are added to the milk, and at no time is sufficiently high temperature used to change any of the component parts. The residues are not yellow or gummy, as milk residues are so prone to become. The protein when obtained by itself is a white powder. After the fat and protein have been completely removed from a single sample of milk the re-

maining portion, which has been named the third fraction, contains the lactose, part of the salts, and a material or materials which for a long time have been spoken of by chemists as extractives. The problem that remains is to find some solvent or something else that will make it possible to separate in a pure state from this third fraction the lactose or the extractives. Our efforts to do this have as yet been unsuccessful, although a part of the extractives have been separated by precipitating with ether, as has been described. The precipitated portion of the extractives thus obtained contains, as has been said, a crystallizable substance whose nature we do not recognize, but whose presence in milk has been heretofore unknown. It has been obtained only in such minute quantities that it has been impossible as yet to make any conclusive study of it.

From the point of view of the physician the results of the analysis of human milk are important in that they seem to prove the essential correctness of the conclusion reached many years ago from the analyses made by Meigs that the amount of protein in human milk is always small, only about one per cent., and to confirm also the conclusion that human milk does not change very greatly during the course of lactation. We have analyzed a good many samples of human milk, both samples of milk from one woman and samples of the mixed milk of a number of women, and have never found any that contained much more than one per cent. of protein, nor have we found any reason to think that human milk changes greatly in quantitative composition during the course of lactation. The milk of a woman whose baby is six months old does not seem to be materially different from that of a woman whose baby is one month old. In the writings upon the subject of the composition of human milk it is often assumed that the milk becomes stronger as lactation progresses. Therefore physicians generally advise that in artificially feeding infants the food be increased in strength from week to week and from month to month. There is no good reason to think that in the lower animals the milk strengthens from month to month during lactation. The young calf probably obtains more milk as the weeks go by because the cow yields an increasing amount up to a certain point, but it does not increase in strength. If the young animal does not obtain sufficient nourishment by sucking its mother, or some other form of nourishment is desirable, it obtains this by picking up small quantities of the same foods as are eaten by its mother. A parallel to this would seem to indicate that in the artificial feeding of infants their principal food, which in civilized countries is made in imitation of human milk, should not be increased in strength from week to week and from month to month, as is commonly taught, but should be given in the same strength but in increased quantities during the first few months of life. This method has been advised by Meigs upon various occasions, and especially in an article published in 1902.*

Most of the resemblances and differences between human and cows' milk are in a general way pretty well known, but on the other hand information upon the subject has not been formulated and recorded so that it is easily accessible to physicians. It is important that every one who is concerned in directing the artificial feeding of infants should be accurately informed in this regard. Human milk is the best food for infants, and it must therefore be imitated, and cows' milk forms the basis of almost all of the artificial foods used. The amounts of water, total solids and fat are not very different in the two kinds of milk. The average amount of water is a little higher and the total solids a little lower in human than in cows' milk, but the difference is not great. Fat is perhaps a little higher in cows' than in human milk, but this difference also is slight. (By a curious chance the two completed analyses that we give contradict our statement in regard to the slight differences between the amounts of water, total solids and fat generally found when human and cows' milk are compared.)

Most common cows give small percentages of fat, and there are a great many more common than there are high-grade butter cows. The amount of fat, therefore, is perhaps little if any higher in average cows' than in human milk. In artificial feeding the difference in the fat percentages, if there be any, may safely be ignored. It is in the amounts of water, total solids and fat, therefore, that cows' and human milk resemble one another. The differences are in the percentages of ash, protein and lactose. The percentage of ash, which is the salts, is about three times as great in cows' as in human milk. This difference is so well known that it is not necessary to dwell upon it. The differences between cows' and human milk that are of importance are those of the percentages of protein and lactose. The importance of these differences lies in the fact that they are not at the present time known by everyone to exist, and because, assuming that their existence is certain, the food value and the digestibility and possibility of assimilation of the two kinds of milk must be very different. This, if true, makes it certain that pure cows' and pure human milk cannot safely be interchangeably used as food for infants. That pure cows' milk is not a proper food for the young human infant is now almost universally accepted by physicians in the civilized world to be a fact. The general acceptance by physicians as correct of analyses which rate the percentage of protein in human milk as high as three or even four per cent. shows that the differences of the two kinds of milk in the percentages of protein and lactose contained are not known and understood as they should be. An examination of the figures of our analyses shows at a glance the difference in the percentages of protein and lactose. In human milk the protein is much lower and the lactose much higher than in cows' milk. It is a curious fact that the sums of the amounts of protein and lactose in human and cows' milk when they are added together are nearly equal. The way in which this fact of the equality of the sums of the amounts of protein and lactose in human and cows' milk has been the cause of the failure for many years of an attainment of a general understanding of the composition of human milk was long ago pointed out by Meigs in a paper called "Proof that Human Milk Never Contains More Than About One Per Cent. of Casein."* It was stated at the beginning of this paper that the principal reason the work was undertaken was to show the accuracy or inaccuracy of analyses of human milk that were published many

*"Analysis of Human Milk the Basis of the Artificial Feeding of Infants." Transactions of the College of Physicians of Philadelphia, Vol. XXIV, 1902, page 136.

*Transactions of the College of Physicians of Philadelphia, Vol. VI, page 92, 1883-4, and "Milk Analysis and Infant Feeding," page 38, by Arthur V. Meigs. P. Blakiston, Son and Co., Philadelphia, 1885.

years ago. It does seem to us that the evidence brought to light by two years of work at the subject comes very near to proving that those analyses are in all essential particulars so nearly correct that the generalizations drawn from them should be accepted. It is as a guide to an understanding of the best method for the artificial feeding of infants, when unfortunately they must be artificially fed, that an accurate knowledge of the relative composition of human and cows' milk has its greatest value. It is upon this knowledge alone that must be based any reasonable understanding of the subject, and without it infants can be artificially fed only as the result of experiment.

TRUNK ANESTHESIA.

A CASE OF MUTISM FOR SEVEN MONTHS—FORCIBLE CLOSURE OF THE LIDS FOR THE SAME TIME—UNWILLINGNESS TO TAKE FOOD IN THE PRESENCE OF OTHERS FOR NINE MONTHS—ALL CURED IN TWO WEEKS BY SUGGESTION, UNCOVERING EVIDENCES OF ABSCESS IN THE RIGHT SIDE OF THE BRAIN, PROBABLY DUE TO OTITIC ORIGIN—OPERATION, RELATIVE RECOVERY.

By BAYARD HOLMES, M.D.,

CHICAGO.

Gale D—, 18 years old, the younger of two brothers, was born at Whitefield, Ill., and has always been a well though not a very strong boy. He was active in spirits until 13 and a good shot and devoted hunter. He was bright in school, but rather bashful. He was tall and weighed about 145 or 150 pounds. His father is a blonde, German appearing man, weighing nearly 200 pounds, who has healthy brothers and sisters, but two uncles who have become insane in their old age. His mother is a brunette weighing about 95 pounds and has been troubled for many years with indigestion and sick headache. It is easy to make a diagnosis of gallstones in her case. Her family is a rather sturdy, active and wide-awake lot of people, without any hereditary taint of any kind except possibly two cases of consumption.

During the summer of 1905, when he was about 13 years old, Gale met with some accident which his family looked upon as trifling. He looked upon it as the cause of all his trouble. In September, 1909, he came to Chicago and consulted Dr. William E. Quine, who said that the boy had heart disease and that he ought to go home and remain in bed for some weeks.

While in bed his father discovered that there was a very bad smell coming from the bed and after close inquiry found that the boy was troubled with a suppurating paraphymosis. He was circumcised by two doctors from Henry, Ill., but the wound did not get well until April, 1910. During this time he remained much in bed and got into the habit of eating in his room and refused to eat at the table with the family.

Some doctors known as Chiropaths took him to Davenport, Iowa, and kept him there for two months. About the first of July he escaped from the Chiropathic place and ran some distance in the street and pounded his own head with a brick or stone. He was said to be running for the river to drown himself. When he was picked up by the police he was carried to a Catholic hospital. The hospital authorities telephoned his father that he was in a dying condition and that he could not be removed, but on July 6 he was taken home, a distance of more than fifty miles, in an automobile.

When he got home Dr. Hess saw him and found that he was dreadfully emaciated, that he had sores on his lips, and that he had retention of urine, involuntary discharges from the bowels, with rapid pulse and low fever. He was placed in a tent in his father's dooryard and carefully attended to. On his arrival from Davenport he was perfectly mute, his eyes were forcibly closed, he refused to move, or at least did not move in any person's presence, and lay in a comatose condition all the time. He could not be fed, but if a meal was set by the side of his bed he ate it. During the months of July, August, and September he made great improvement and was believed to weigh as much as 135. During all this time he never spoke except once, when he called for more to eat to his mother, who was just outside. He never ate in his mother's or father's presence and no person visited him except Dr. Hess. During all this time, also, he never opened his eyes in any person's presence. He was quite tidy after the first two weeks at home and used the chamber which was kept conspicuously by the side of his bed. He had always been myopic and he wore his glasses all of the time except in the night. He never took them off himself, but he would put them on early in the morning. Dr. Hess considered it a case of dementia præcox, but claimed no special skill.

I first saw the patient with Dr. Hess on February 9, 1911. Gale's eyes were closed, he lay in bed with a pulse of 88 and a normal temperature. On raising the lids the pupils were seen to be distinctly dilated. They responded sharply to light and seemed to be equal in every particular. I found the abdominal, the scrotal, the patellar, and the ankle reflexes normal, or thought them so. There was, however, almost complete anesthesia from the neck down, except upon the fingers and toes and the bottoms of the feet. I was able, without his flinching, to thrust needles through the skin that I picked up on his arms and legs. However, he did respond to light touches and seemed to enjoy having his legs moved passively. I was unable to get him to open his mouth or to speak a word or swallow a particle of water or milk. Nevertheless, while I was out of the room he ate a moderate breakfast. After breakfast I went over the examination again and concluded it was a case of hysteria. I alarmed his family by asking for his clothes and after dressing him I placed him on a horse and took him for a little ride. When he came back alone with the horse he was holding the lines and his brother said his eyes were wide open as he approached the barn.

A short time later I brought him to Chicago. He walked to the train, from the train to the carriage, and from the carriage into the hospital. On admission he weighed 95 pounds. For three weeks previous to his entrance to the hospital he had vomited every time any one went into the room and he had lost greatly in weight and strength. His eyes were closed, it was impossible to get him to open his mouth except by force, and he would not drink or eat anything even though it was left near him. During the first twenty-four hours in the hospital his stomach was washed out three times a day and filled with a pint of eggnog. Every time he vomited this eggnog another pint was put in his stomach with a stomach tube. At night he had a large enema consisting of four quarts of hot water, twice repeated one after the other. On the second

day I suggested to him that he could open his mouth and eat and so far succeeded, with the help of Dr. P. G. Kitteman and two nurses, that we were able to feed him a full meal of solid and liquid material. We suggested at the same time that he could not vomit this and he did not vomit after that time. Twenty-four hours later we suggested to him in the same manner that his eyes would open and they did open and have remained open ever since. He walked around the hospital from room to room. He was still anesthetic and I frequently demonstrated this anesthesia to physicians. He was still mute and I suggested that three days later he would begin to talk. He did begin to talk and since that time has responded to questions after considerable urging and has shown some emotion, crying about his conduct on two or three occasions. At the end of the second week his physical examinations had shown a pulse continuously in the neighboorhood of 120, his temperature was slightly fluctuating and was taken by the rectum. It was not more than a degree above normal at any time and never subnormal. From the time that he entered the hospital up to the end of the third week there were frequent occasions when his breath was distinctly strong of acetone. During all this time he had a leucocytosis of 12,000 to 24,000—one count which must be looked upon as absolutely reliable was only 4,400. The polymorphonuclear neutrophiles were 89 per cent. and there were no eosinophiles.

About two weeks after he came to this hospital the results of our examination showed a uniformly high pulse 110 to 120, a uniformly increased leucocytosis, 12,000-24,000, a blood-pressure of 120, a stationary weight in spite of forced feeding, and a hebetude which was hard to overcome and from which it was difficult to arouse the patient to answer questions. He now began to fall down when walking, but never in a manner to suggest a lack of equilibrium. It seemed that the falling down was the result of a suggestion made during a visit to one of the patients who had a resected knee. Two or three shocks from the coil restored his legs to activity, and he would walk around and only fall in the presence of other people. During ten days he had hot and cold spray to the back and general massage. During this time he talked with the masseur, Mr. Grimstead, and told him a great many things about his mental life during the time he was mute and had his eyes closed. He felt very sorry that he had caused his family so much trouble, and cried on several occasions.

Mental and Neurological Examination by Dr. Ralph Hamill of Gale D—, Saturday, February 25, 1911.—Patient just returned from hydrotherapeutic treatment. Speaks in whispers, answers sometimes prompt, sometimes delayed, usually correct and to the point, occasionally a tendency to show relevancy without exactness (suggesting Ganser symptom). Asked if he ever heard voices said, "Yes, sometimes." "Whose are they?" "I don't know." "Where do they come from?" "The next room." "Where else?" "The hall." "What do they say?" "They tell me to quit." Another time: "Quit it." "Quit what?" "Seem to know what I'm doing." "What were you doing? Were you doing anything bad?" "They told me to stop when the stuff was running out of me." "What do you mean?" "When I soiled the bed." "What else did they say?" "They told me to let it alone." "What do you mean?" No answer. Finally it came out that a voice seemed to come through the door of the bathroom telling him to stop masturbating. Thinks it might have been the voice of a servant, *i. e.* hospital orderly, though he says the door was closed. Asked why he stopped eating, said it was because he thought that might stop his soiling the bed and vomiting. Answered that voices seemed to tell him to stop eating. Oriented fairly well as to time and surroundings. Asked to shake hands, made no move. Examiner's hand held directly over his hand, no move, with slight pressure beneath his hand it was gently started toward examiner's hand and patient completed the act. During the examination patient's behavior was completely free from motor acts, simpering, foolish smiles, turning of the head, etc.

Stroking the left foot sole caused first slight plantar movement of entire great toe with subsequent slow dorsal flexion. After two or three strokes, motion was entirely dorsal. Right always plantar. No Achilles reflex, no knee reflexes. Patient could not be made to use Jendrassik. Wrist, biceps, and triceps taps reduced but equal. Abdominals reduced and equal. Cremasterics ditto. At times pupils showed slow contraction and relaxation; reacted well to light and convergence. Patient could not be gotten to make extreme lateral movements with the eyeballs. Lesser movements showed no abnormalities. Ophthalmoscopic examination showed nerve heads white, no physiological cups, outlines very indistinct, vessels approximately normal. No apparent difference in cranial nerves. In attempting to walk with support, legs tended to hyperextend at knees, but all movements are very feeble. Passive movements are resisted. No apparent abnormality to coarse sensory tests. Diadochocinesis could not be tested for. Fine tremor in both hands. Turning chin over either shoulder causes no dizziness nor nystagmus. Visual fields + to finger test. No hemianopsia.

February 27.—Patient just returned from laboratory. Reflexes as above. Patient would not answer questions. Attempts to make him follow with eyes to lateral positions unavailing. When the chin was turned over either shoulder by the examiner the patient would maintain position indefinitely. The patient can tell the color of flowers, red; also the color of paper cover on the flower pot, green. He writes his name here.

Both pupils react to light and accommodation and dilate on stimulation of the sympathetic, pinching the cheek. The media are clear. The optic nerve heads are too white—a greenish white, the outlines of the nerve head are gone. There is no physiological cup; the nerve heads are slightly swollen. The relative size of veins and arteries is out of the normal—veins too large, therefore, secondary optic atrophy.

On February 22 the same examinations were conducted by Dr. Pusey and the previous findings confirmed. He said at that time, and wrote upon the history, "This probably means a localized process in the cranial cavity and a recessive one, such as an encapsulated or absorbing abscess. The duration of the process that has caused the optic atrophy could hardly have been less than two months. The atrophy is more marked on the right side; the swelling of the nerve head is a little more marked on the left side. According to Horsely, this would mean a right-sided lesion." The patient was weighed at this time and found to weigh only 96, stripped. All the blood, urinary, and serolytic examinations were repeated. Dr. Dennis examined

the ear drums and considered them both normal except for retraction. There is no indication of perforation.

Several test meals were given and one of them, on February 6, is recorded as follows: Ewald, 30 c.c. brown color, two layers well digested in fine state of division with no frothing. It had a sour odor on removal. There was no swallowed mucus and only a moderate amount of stomach mucus. There were no blood clots or pulpy ground material, and no fragments of mucous mebrane. The microscopical examination showed a few squamous epithelial cells, but no cylindrical cells or pus cells, no blood; no Opler-Boas bacilli, no sarcinæ; a few yeast cells and a few other bacteria; no muscle fibers, but a few starch granules. The clinical examination showed an acid reaction to litmus and to Congored. The total acidity was 30. The dimethylamidoazobenzol hydrochloric acid reaction was negative. There was no free hydrochloric acid, but a moderate reaction to lactic acid. No blood and no bile.

The examination of the urine was repeatedly made and was quite uniform. Just before the operation a single specimen was of an amber color, of slightly acid reaction with no sediment, slightly cloudy, strong urinous odor, specific gravity 1.025, with no albumin, no sugar. The urea was not estimated and there were no other abnormal constituents. The centrifuged sediment contained no casts and no blood cells, very few pus cells, occasionally squamous epithelium, and a few mucous shreds.

The blood examinations, as we have previously mentioned, varied between 5,260,000 reds, 24,400 white, 14 per cent. lymphocytes, 86 polymorphonuclear neutrophiles, hemoglobin, 85 per cent., Dare; and 4,700,000 reds, 4,400 whites, 17 per cent. lymphocytes, 13 per cent. large mononuclear, 69 per cent. polymorphonuclear, and 1 per cent. eosinophiles. Several blood cultures were made and all found negative. There were no indications of endocarditis, as repeated examinations of the heart showed, and no evidence of enlargement of the spleen and liver. No stools were examined.

It seems that the following negative results of our examination can be distinctly set forth: (1) There is no tuberculous disease in the boy's body, as the careful and repeated examination of the lungs, the testicles, the two kidneys, the seminal vesicles, and the lymph apparatus generally demonstrates. The condition of the blood (leucocytes 12,000-20,000), the negative effect of tuberculin injections, and the Pirquet reaction all are against tuberculosis. (2) There is no evidence of septicemia as demonstrated by two blood cultures, by the absence of auscultatory signs of endocarditis, by the absence of bacterial nephritis, by the normal size of the spleen and liver, by the absence of tenderness over the appendix, the gall bladder, the liver, and the kidney region. (3) There is no local infection in any extremity as demonstrated by careful examination of the digits, the joints, and the inguinal and axillary lymph glands. (4) There is no infection in the chest or abdomen, as a careful examination of all of the accessible and probable foci clearly demonstrated. (5) There is no serious blood disease such as syphilis, lead poisoning, chlorosis, or the more conspicuous parasitic infections, since there is no abnormality in the blood or lymph apparatus, and the Wassermann test is distinctly negative. (6) There is no contraindication in the condition of the heart or the lungs to a general anesthetic. (7) There is no evidence of disease of the cord.

It seems that the following positive indications exist as a result of our combined examinations: (1) The leucocytosis, the slight variation in temperature, the history of sweats, all stand for a pyogenic infection. (2) The condition of the fundus, the pupillary conduct and reaction, the absence of patellar reflexes, the occasional tremor, the presence of Babinski, all localize the infection inside the cranium. This is also consistent with the mental hebetude and the secondary psychosis. (3) The absence of vertigo and incoordination, and the absence of localizing motor symptoms suggest the hypothetical abscess in the frontal lobe or at least in the cerebrum. (4) The Babinski on the left side, the condition of the fundus oculi, the history of the suppurative otitis media, all suggest the abscess upon the right side of the brain and in the right cerebrum. (5) The presence of acetone in the urine and the peculiar odor of the breath are all significant of abscess of the brain.

Taking all these positive and negative findings into consideration, we must say that the great probability is a pyogenic infection in the right half of the calvarium from an antrum disease which may or may not be associated with a hemorrhage or incysted hemorrhage in the neighborhood of the petrosa, due to the accident which occurred in 1905, six years ago.

There are three distinct forms of infection which must be looked for, a sigmoid sinus thrombosis which may extend into the neck and obliterate the jugular, or may extend to the torquelar and up the superior longitudinal sinus, or may extend from the torquelar to the left and obliterate the lateral sinus on that side; in the second place it may consist of an extradural abscess in the middle fossa (this may be directly connected with the sinus thrombosis); or in the third place it may be due to a true cerebral abscess which has arisen from the migration of bacteria from the petrosa into a residue of hemorrhage due to the accident or into a non-resisting space in the frontal lobe, the tract of which infection has now become perfectly normal tissue.

The course of the operation should then be an ordinary évidement of the mastoid, opening of the sigmoid sinus, the obliteration of any infection thus discovered by a ligation of the jugular deep in the neck and the opening of its peripheral end in the upper corner of the wound after the ligation. In the absence of sinus thrombosis, the middle fossa should be opened to discover any extradural abscess which may have arisen from the perforation of the antrum or the tegmen tympani. If no extradural abscess is found then the middle lobe and the frontal lobe of the brain should be carefully explored with the aspirator and the latter approached through a second opening in the parietal region in front of the ear. A sinus thrombosis of such extent may be treated by the method of canalization which I suggested in the *Journal of the American Medical Association*, January 13, 1906.

Seven skiagraphs were made of the head in various positions. Dr. Lewis and Dr. Max Richmann thought that there was indication of a fracture six inches behind the glabella, about an inch and a half in extent, but subsequent skiagraphs did not support this diagnosis, and when the operation was performed no evidence of such displacement of the lower table of the skull could be determined.

The mental condition of the boy was not such as to make it possible to examine the condition of his internal ears. The only thing we could feel confident of was that there was no vertigo or other symptom which would indicate disease of the labyrinth.

I had the support and advice of Drs. Brown Pusey, Ralph Hamill, Besley, Dooley, Howard Hess, and several visitors during the operation.

The patient was prepared for the operation by shaving the head completely and giving the ordinary intestinal flushing. Under ether anesthesia the right mastoid was approached by the usual incision, the fleshy meatus was cut across, and the ear was turned over onto the face. The posterior part of the mastoid was then rapidly chiseled away with a large chisel and hammer. The air cells were found to be of enormous size, the walls extremely eburnated, but no evidence of pus in any of them, or even of an old infection in the form of cholesteatoma or residue.

With a smaller chisel the antrum was carefully approached, and found equally empty of infectious residue. In the course of these procedures the sigmoid sinus was exposed for three-quarters of an inch. It showed no evidence of infection. The middle fossa was now opened in close proximity to the antrum. The dura gave no evidence of thickening or of any infection. A small slit was made in the dura and a considerable quantity of serum poured out. A blood vessel of the pia was accidentally wounded, which made it necessary to pack this wound to stop the blood. The sigmoid sinus was now opened with a Hagedorn needle. It bled freely, showing that there was no thrombus in the sinus. The wound was now packed with a strip of iodoform gauze and the incision was closed, bringing the ear back into place.

We now made an incision over the posterior part of the frontal lobe and the frontal part of the middle lobe, reaching down to a point immediately in front of the middle meningeal artery, giving us a flap two inches and a quarter long and an inch and a half wide, with its base containing the branches of the temporal artery. The bleeding was trifling and was controlled with forceps. A smaller incision was made in the skull with the small trephine and a de Vilbis machine. When the flap of bone was turned up it broke, but hung by the temporal muscle, which was attached to its lower half. The surface of the brain did not protrude as if under great pressure. The dura was white, smooth, and unattached to the surrounding skull. Two small incisions were made in the dura and the meningeal fluid poured out rather freely.

The aspirator was now introduced for a distance of two and a half inches into the brain and toward the base, and two drams of a clear fluid, believed to be meningeal fluid, was withdrawn. It had no odor. More than 20 other punctures of the brain were made in all directions, and only once was any fluid withdrawn. This was in the direction of the frontal portion of the middle lobe of the brain. This fluid was examined by Dr. Bulig and was believed by him to be cerebrospinal fluid, and without any evidence of infection. The bony flap and the scalp were now returned to their places and closed without drainage.

The patient vomited two or three times after returning to his room, and the last time he called for a basin. This was the first time he had asked a question or demanded anything since he came to the hospital four weeks previously. During the afternoon he asked for water and conversed with his nurse and his father. He had a much more human expression upon his face, and when he answered questions he gave extended answers which involved considerable thought. His father told him that he had moved to Henry, and he replied that he told him last week he was going to do so. His father asked him if he knew what house he had bought, and he said, "Why, yes, of course. You told me when you were here the last time that you had bought the Gregory house."

When I visited him in the evening he told me that he was feeling quite well, but that the side of his head was a little sore, and that it hurt him to bend his head on his neck. He told me that he was not dizzy to amount to anything, and that he would like to sit up on the side of the bed. When we brought him to an erect position he said that he was dizzy and volunteered this information and asked to be allowed to lie down again. His pulse was 114, his temperature 99°, and his respiration slow. He had a trifling cough and expectorated with some distress on account of the pain in his neck.

The first night after the operation he slept perfectly well, and was relieved of the mucus in his stomach and intestines, and became hungry. He asked without suggestion for something solid to eat, and had a long conversation with his nurse and his father. A good many nurses and doctors called on him during the day and he spoke to each of them pleasantly. He talked for a half hour with his interne, Dr. Hall, and described his father's farms and gave their value and what was raised on them. On the evening of this day his temperature rose to 101°, but fell again without any medical treatment.

On the morning of the second day he was just as bright as ever, and his head was dressed, and it was found dry and apparently united, except where the drain from the mastoid protruded in the neck. Dr. Pusey examined his fundi and found them in the same condition as before the operation. He demonstrated the potency of every muscle of both eyes, and the normal reaction of the pupil.

Immediately following the operation the patient made great improvement in his appearance and his interest in the outside world. At no time after the operation, either in the hospital or since he returned home, has he had involuntary discharges from the bowels or from the bladder, and he has been perfectly tidy. He went with his nurse to the theatre two weeks after the operation, paid the street car fare, and conducted himself properly. He seemed to enjoy the performance and expressed himself vivaciously and rationally at all times. He returned to his home on March 30. At that time there was only slight improvement in the appearance of the retina, but the Babinski had entirely disappeared.

After returning home the improvement continued and the patient was able to meet all the requirements of his home life, taking good care of himself and his room, and doing chores about the house. He complained of weakness in his leg, and on measurement the calves were found distinctly smaller and softer than they ought to be for a boy of his size. On leaving the hospital he weighed 119½ pounds, having gained almost exactly 20 pounds since the operation. He has made a further gain of 15 pounds, and has maintained a steady

weight above 135 for more than three months. On December 1 he weighed 160 pounds in light shoes and without overcoat.

There has been a distinct improvement in the expression of his face, and he has shown renewed interest in the newspaper, especially the sporting pages, in romantic literature, and in substantial history, which was formerly his great delight.

During the past summer he has suffered consecutively the loss by suppuration six of his toe nails, beginning with the right big toe, and this in spite of superior surgical precautionary treatment.

This was either a case of dementia præcox or it was not. If it was of this nature then we are warranted in assuming that the hysterical symptoms which disappeared so promptly on suggestion, namely, the forcible closure of the eyes, the mutism, the persistent vomiting, and the refusal to take food, were of a more superficial nature than the remarkably general anesthesia which remained in spite of suggestion. There must, moreover, have been some serious condition which prevented the patient from gaining weight previous to the operation, which was in some manner removed by that procedure. Again, his constant untidiness before the operation and his habitude disappeared promptly after his recovery from the anesthetic. It is my opinion that the amount of fluid removed from the cavity, natural or unnatural, was insufficient to produce compression. Moreover, there was no evidence of compression when the dura was exposed.

The possibility of a tuberculous chronic meningitis which was jogged out of place by the operation is not supported by the frequent tuberculin tests, by the condition of the fluid withdrawn from the center of the frontal lobe, or by the condition of the leucocytosis.

The subsequent history of this patient will be of great interest, and if it is a fact that dementia præcox is an absolutely progressive, destructive disease, with an invariable tendency to extreme dementia, then time will complete the diagnosis. In the present state of our knowledge of the etiology of this disease, no further tests or evidence can be expected.

Since the patient is now in a perfectly rational conversational condition, it would be interesting to see what the Freud and Jung psychoanalysis would show.

108 North State Street.

CHRONIC INVALIDISM DUE TO PATHOLOGICAL CONDITIONS OF THE COLON AND APPENDIX.*

By JAMES TAFT PILCHER, M.D.,

BROOKLYN, N. Y.

There are two conditions in the abdomen presenting pathological entities, which though existing for many years in the majority of cases, have been persistently overlooked as the etiological factors of the chronic indisposition which the patients complain of, and have in too many instances caused a chronic invalidism. I refer particularly to chronic inflammatory processes in the appendix, which present little or no local subjective disturbance and to the definite fecal stasis in the large bowel consequent to deformities of it caused by pericolic inflammatory films. Anything that can throw light upon the symptomatology of these conditions and which would lead to an earlier recognition of its causes must be of importance.

Persistent recurrent indigestion has for many years been treated as if it arose from conditions in the stomach itself and the measures directed against it have been as a rule local in their effect and have proved ineffectual, as demonstrated by the recurrence of the distress at a later date. The fact is beginning to be appreciated that primary disturbance of the functions of the stomach is very infrequent. As illustrative of this contention the author, in examining something over eight thousand patients complaining of stomach distress, was able to find approximately but 10 per cent. of the cases in which the condition was primarily caused by some organic change in that viscus. In the remainder, correction of the extragastric factor which was reflexly causing the stomach symptoms, as chronic appendicitis, cholelithiasis, colecystitis, inflammation of the intestinal tract in any of its parts, etc., sufficed promptly to ameliorate and in many instances entirely to stop the gastric distress.

Of great interest is that distress reflexly produced in cases of chronic appendicitis, and this is quite readily recognized as the etiological factor in the majority of cases. The duration of the distress referred to the stomach by these patients averages many years. If the history is traced back far enough a large percentage can be found who even in childhood suffered more than other children from frequent "stomach aches," "cramps about the navel," and unexplained attacks of "diarrhea." This triad undoubtedly represented the inception of the appendical inflammation.

After a few years short spells of transient epigastric distress ensued, usually ascribed to "catching cold" or "some indiscretion in diet" or "overexertion." Certain kinds of food caused distress. There was belching, slight nausea, and a bloated sensation in the "pit of the stomach." After a few days or a week the patients regained their normal health. After a period of years when they had attained young man or womanhood, the periods of discomfort became more frequent in their occurrence; they lasted longer, the distress was more severe, and the interval of freedom not so complete. There was always some discomfort in the abdomen.

The relation of food to the distress is noteworthy in differentiating the symptoms from those of ulcer, with which the condition is frequently confused. Its ingestion usually *increases* the discomfort, while in ulcer food temporarily relieves the pain. The distress is peculiar in its character. It is indefinite. In most cases it is possibly described best as a bloated sensation over the entire upper abdomen. At times these patients experience epigastric cramps which we now appreciate are due to a spasm of the pylorus, which structure can frequently be palpated momentarily, only to have the tumor disappear while yet under one's fingers, as the musculature relaxes.

Vomiting is occasionally complained of and at times remnants of a former meal may be found if the pyloric spasm has been continuous. Nausea is, however, a much more frequent symptom. Belching is of little diagnostic import, though usually present, and while acid eructations are frequently noted they are not of such a definite character as those present in cases of ulcer, although I have noted instances in which they were very frequent and persistent.

*Read before the Second District Branch of the Medical Society of the State of New York, October 26, 1911.

In the gastric analyses of several hundred patients exhibiting the above phenomena the only finding of interest was the frequent occurrence of a hypersecretion and a tendency to a very slight increase in the hydrochloric acid contents. There were, however, several cases with marked diminution of the acidity and even a complete absence of it.

It is rather exceptional to have one of this class of patients mention any subjective sensations referable to the right iliac fossa, all of their complaints being centered on the distress in the epigastrium, and, indeed, frequently no tenderness can be elicited on pressure over the appendix. But that is not absolute evidence that it may not be markedly diseased. Fortunately the opposite is the case in the majority of patients and deep pressure over McBurney's point will usually cause some discomfort, and, what is particularly distinctive, deep manipulation of the cecal region has been observed in some instances to elicit a renewal of the epigastric distress previously complained of.

Much may be accomplished by the judicious introduction of medical and dietetic measures to relieve to some degree and occasionally to cause the complete disappearance of symptoms from which these patients suffer. Each case must, however, be treated on its own merits and the degree to which the disease has progressed must be taken into consideration.

In general, methodical lavage is an important item of treatment, especially where there is a disturbance of the gastric motility present, and if one dram of sodium bicarbonate be added to each quart of water used, the results seem to be better. A course of Carlsbad salts or, if possible, a few weeks at one of the mineral springs is beneficial. Care should be taken, however, to interdict the use of too large amounts of these mineral waters. Massage is absolutely contraindicated owing to the pathological process present, but if evidence exists of dilated or prolapsed organs these should be supported by an appropriate binder. Much relief may be afforded by the proper arrangement of the diet. This should consist principally of amylaceous substances which are not predigested and which are not digested in the stomach in order not to stimulate the gastric activity. The addition of fats, cream, and oil to the dietary is a most essential adjunct. Moderate amounts of green vegetables may also be given.

We have found bismuth carbonate or subnitrate in combination with calcined magnesia to act most favorably, not only as an antacid, but as a real gastric sedative, when administered two or three hours after meals. Diastase may be given with the meals with benefit.

Thus by careful medical supervision through symptomatic treatment and the suppression of the more urgent symptoms many patients may lead a moderately comfortable life, but sooner or later in a large number the onset of complications or an exacerbation of the causative factor necessitates surgical intervention, the results of which have been most encouraging. In the cases in which the appendix was removed and which have been followed up to find out their present condition, 75 per cent. have absolutely no complaint whatever; 15 per cent. are very much improved; 5 per cent. have occasional recurrences, and 5 per cent. are unimproved.

The second condition to which I wish to draw attention is the symptomatology of chronic intestinal stasis. The increasing importance attached to the general effects produced by the continuous absorption of poisons formed within the body, especially those elaborated in the large intestine, is one of the most striking features of practical pathology as applied to clinical practice in the present day.

The physical signs and symptoms indicating a condition of stagnation, particularly in the colon, are quite unmistakable, but seem until lately to have been disregarded or possibly incorrectly interpreted. Peculiarly it is seldom that patients suffering from this condition consult the physician because of the fact that they are habitually constipated, but more frequently their chief complaint is that of abdominal discomfort, to which they ascribe their chronic invalidism, and it is to be relieved of this that they primarily seek advice. This discomfort varies much as to the degree and situation. It may be intense and continuous or intermittent and mild. Its position is seldom described as being at a definite spot. More frequently the whole hand is laid on the abdominal wall to indicate the extent of the distress. In the large majority of cases it is referred over the course of the ascending colon and tenderness or pressure over this area is usually noted.

Subjectively these patients present a symptomatology consisting usually of the following ten cardinal factors:

1. *Constipation,* usually persistent and necessitating constant employment of laxatives. As a rule the bowel has become so tolerant that many of these patients can go several days without any inclination to defecate.

2. *Mental apathy,* at times so marked as to cause a state of stupor. Symptoms of melancholia are not infrequently present. They are unable to center their attention on any one thing for long, and, as they state it, "they feel as if they had lost all ambition and can do no work."

3. *Cold and clammy hands and feet* as evidences of sluggish circulation. A marked slowing of the pulse to forty or fifty is also to be noted.

4. *Headache,* usually vertical and occipital, which is frequently severe in character and frequent attacks of vertigo occur, which in some has been their chief complaint.

5. *Anorexia* is almost always present.

6. *Nausea* and even repeated vomiting are complained of.

7. *Loss of weight* is always noted.

8. *Foul taste in the mouth,* accompanied by a furred tongue and carious teeth.

9. *Myalgia,* especially referred to the muscles of the extremities, particularly the legs, and also pains in the joints, which are usually ascribed to rheumatism.

10. *Bloating,* occasioning at times severe discomfort.

All of these symptoms are temporarily improved when free movement of the bowel is evoked, only to recur when the feces reaccumulate in the colon. On inspection of such a patient one almost invariably notices a sallowness or irregular brownish pigmentation of the skin, more marked probably at points where there is pressure from the clothing and in the groins, axillæ, or under the eyes. The breasts are usually atrophic and flaccid in women and tend to undergo cystic degeneration, being particularly liable to the future development of malignant degeneration.

On palpation of the abdomen one easily appreciates the tender, dilated cecum and ascending colon in many cases. Ocular demonstration of our infer-

PATHOLOGICAL CONDITIONS OF THE COLON AND APPENDIX CAUSING CHRONIC INVALIDISM.

ences has thus far without exception been offered to us by the intelligent interpretation of *x*-ray plates prepared by Dr. Eastmond.

The pathology causing a continuance of the trouble is indicative of its prolonged course, and the ever-increasing difficulty of bowel evacuation. The appendix and terminal ileum and cecum are bound down to the walls of the right inguinal fossa by strong bands in many instances. In others, in which the symptoms were less severe, a chronic obliterating inflammation of the appendix and in addition a veil or film of tissue covering over the entire cecum and extending up onto the ascending colon were noted. In those in whom the symptoms were of longer duration, and who had reached a greater degree of invalidism in consequence, the chronic productive inflammation which evidenced itself in the newly formed pericolic tissue completely enveloped the entire ascending colon and had drawn down the first part of the transverse colon to which it was closely adherent, thus causing the formation of two acute angles, at which points it was evident the greatest stenosis occurred, and one can readily appreciate the limitation of mobility and the inhibition of the peristalsis which the inflammatory films caused in the colon itself.

Here also the internist may for years successfully combat the more distressing symptoms and in many instances effect a complete return to health through unremitting oversight. The measures usually employed consist in regulation of the diet, intestinal antiseptics, saline laxatives, abdominal massage and support, and colonic irrigation. We have noted at times the introduction of large olive oil enemata, retained over night, to be followed by very marked relief. These should be repeated biweekly. Unfortunately, however, even after the most thorough treatment the patient's invalidism becomes augmented, and it would appear justifiable therefore that after such measures by a medical man had proved ineffectual the opening of the abdomen and liberation of the structures involved should be undertaken, and secondarily, if the symptoms recurred, a resection of the colon and an end-to-side anastomosis between the ileum and sigmoid or upper rectum shall be made, as this procedure has in many instances resulted in a complete return to health of a patient who was otherwise condemned to remain a progressively useless invalid.

As illustrative of the gross pathological findings in the class of cases considered in this paper, the accompanying figures are inserted.

Explanation of Plate. Fig. 1.—Chronically thickened angulated appendix, containing fine movable fecoliths.

Fig. 2.—Longitudinal section of the appendix, showing chronic thickening of the walls, an impermeable partition in the middle, and five fecoliths.

Fig. 3.—Old partial obliteration of the tip of the appendix, with secondary partial obliteration of the lumen recently produced; in the middle is a focus of necrosis with acute inflammation, and at the base is a stricture.

Fig. 4.—Two views, external and internal, of an appendix with bulbous tip containing a large movable fecolith, irritation at the proximal pole of which caused a chronic ulceration with subacute perforation.

Fig. 5.—Extensive involvement of the ascending colon, appendix, and small intestine by newly formed pericolic films (drawn at operation).

THE QUESTION OF TRANSPLANTATION OF THE CORD IN OPERATIONS FOR HERNIA;

WITH A NOTE ON THE ROLE OF THE TRANSVERSALIS FASCIA IN THE PRODUCTION OF ABDOMINAL HERNIA.*

By ALEXIS V. MOSCHCOWITZ, M.D.,

NEW YORK.

VISITING SURGEON HAR MORIAH HOSPITAL, ASSOCIATE SURGEON MOUNT SINAI HOSPITAL.

According to the best statistics a radical cure of hernia can be obtained, in practice, in 95 per cent. of the cases. This rather large percentage of cures is noteworthy, when we consider, than on *theoretical* grounds the majority of herniæ are incurable Surprisingly enough, I refer especially to the most common forms of hernia, namely, inguinal and femoral. By this I mean that every operation thus far devised for the cure of these herniæ, and I feel safe in saying that any operation that may ever be devised, will still leave an opening through which an escape of abdominal contents is possible.

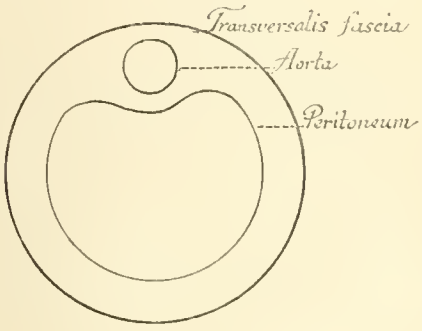

Fig. 1

In order not to be misunderstood, it is necessary to preface my remarks by explaining my conception of hernia. Before proceeding with this explanation a definite understanding of certain underlying and fundamental principles of the anatomy of the abdominal parietes is essential. If the elucidation of my theme may appear somewhat elementary or even prolix, I plead justification for the sake of clearness.

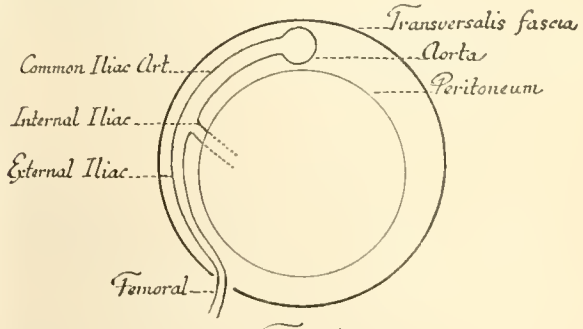

Fig. 2

1. The entire abdominal parietes are lined by peritoneum.

2. Externally to the peritoneum there is everywhere a layer of fascia. This fascia has received different names in different parts of the abdomen, *e.g.* transversalis, pelvic, iliac, diaphragmatic, etc.

*Read at a meeting of the Surgical Section of the New York Academy of Medicine, December 1, 1911.

If traced, however, it will be found that these are merely parts of one continuous layer. For the sake of ready understanding I shall term this fascia, throughout this paper, the transversalis fascia.

3. All the large vessels in the posterior abdomen lie *upon* the transversalis fascia, and are *covered by* the peritoneum. I regard this fact as one of the most important in the proper understanding of the anatomy of hernia. For this reason I shall discuss this subject in detail.

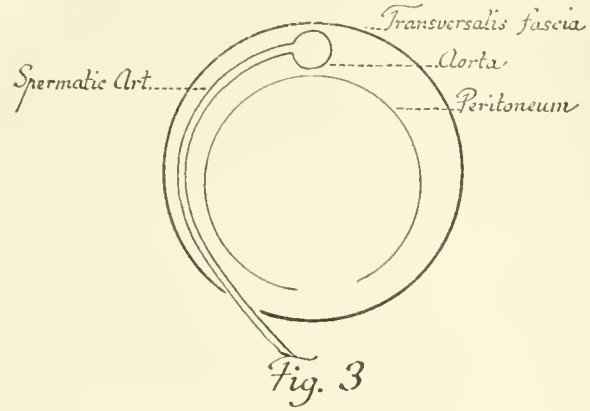

Fig. 3

Fig. 1 represents schematically a cross-section of the abdomen at any point above the bifurcation of the aorta. At the point of exit of the femoral vessels into the thigh, the diagram is modified as in Fig. 2. Fig. 3 is a modification of Fig. 2 and represents the exit of the spermatic vessels. If Fig. 2 and Fig. 3 are closely examined it will be seen that at the point where the vessels lose their relationship to the peritoneum there is an opening in the transversalis fascia, in order to permit the escape of these vessels from the abdomen.

As a matter of fact, however, careful dissection will show that the transversalis fascia is continued downward for a certain distance upon the vessels, gradually becoming thinner and thinner, blending finally with the vessel wall itself. To be exact therefore the last two diagrams should be modified as in Fig. 4 and in Fig. 5.

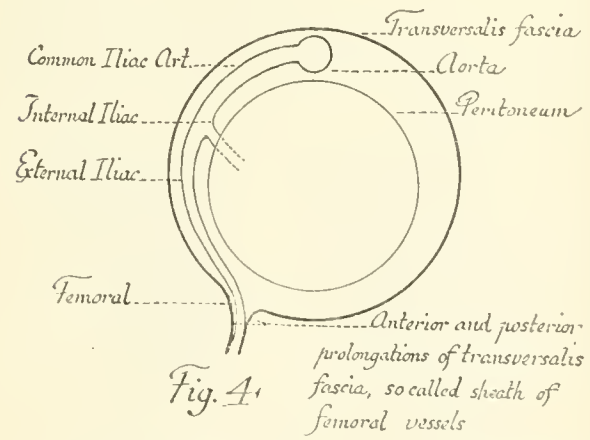

Fig. 4

In certain parts these perivascular prolongations of the transversalis fascia have been carefully studied, are well marked and, indeed, have received special names. I mention as such the prolongation upon the spermatic vessels, which is called the infundibuliform fascia, and the prolongation upon the femoral vessels, which has received the name of sheath of the femoral vessels.

There is no doubt, though it never was stated before, that a similar anatomical arrangement holds true for every blood-vessel that escapes from the abdomen to the periphery, as for instance the obturator or sciatic arteries. Likewise a similar prolongation of the transversalis fascia accompanies all viscera, which escape from the abdomen to the periphery, for instance, the rectum and vagina, which accounts for the occurrence of herniæ in these locations.

Although the importance of the transversalis fascia in hernia has not, I believe, been estimated

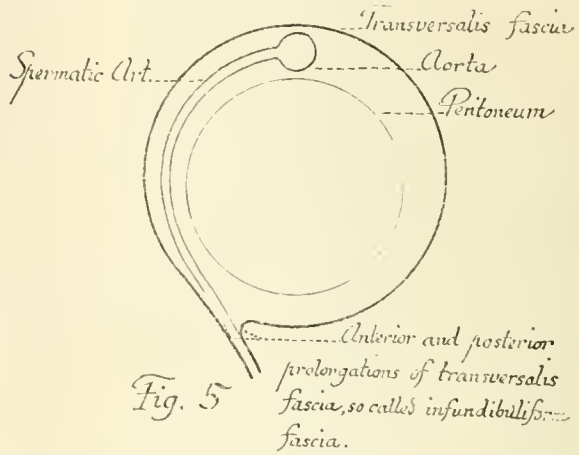

Fig. 5

at its true worth, it is an established fact that this fascia is, as a rule, strong enough to retain the viscera within the abdomen. It is, however not strong enough to do so at certain definite anatomical points; and it is at these points, and at these points only, that we find herniæ. A little reflection will show that herniæ occur only where blood-vessels or viscera make their exit normally. In other words, it is very apparent that these weak anatomical points must be the attenuated perivascular or perivisceral projections of the transversalis fascia. (See Figs. 4 and 5.) Every hernia can therefore be diagrammatically represented, as shown in Fig. 6.

Now in some locations these vessels are small and of minor importance; in others, on the other hand,

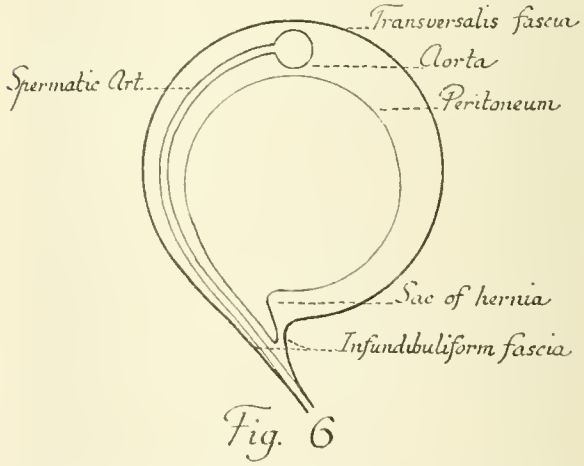

Fig. 6

the vessels are of vital importance to the structures which they supply. Therefore some herniæ are *theoretically* readily curable, because it is merely necessary to divide the vessels and close completely the hole in the transversalis fascia. In other herniæ, however, in which the blood-vessels are of vital importance, *e.g.*, in inguinal hernia (spermatic vessels) and femoral hernia (femoral vessels), these vessels can not be divided, the hole in the transversalis fascia must remain, and therefore *in*

theory these herniæ are incurable. In practice, however, we find that the surgeon gets around the difficulty by ignoring the weak spot in the transversalis fascia, but fortifying it by building a buttress of fascial and muscular structures in front of the opening.

I claim, therefore, that our operation is only a makeshift, and as long as it must remain a makeshift it is of the utmost importance to build this artificial buttress at that point where it will do the most good, *i.e.*, directly in front of the opening in the transversalis fascia, or at least as close to it as possible. This brings me to my original inquiry, when should the cord be transplantedé

Permit me now to present a diagrammatic cross-section of the inguinal region, in order to indicate the anatomy of the two forms of hernia which occur in this region, namely, direct and indirect. By referring to the diagram (Fig. 7) it will be seen

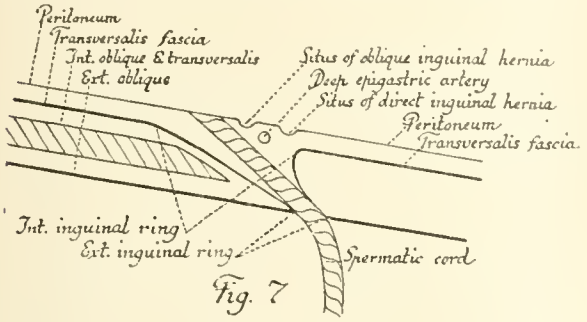

Fig. 7

that the internal inguinal ring (site of exit for an oblique inguinal hernia) is situated to the outer side of the deep epigastric artery. It is somewhat overlapped by the internal oblique and transversalis muscles, and wholly by the aponeurosis of the external oblique, and is situated at some distance upward and outward of the external inguinal ring. Furthermore, it is evident that the internal opening of a direct inguinal hernia lies to the inner side of the deep epigastric artery, directly behind the external inguinal ring, and practically without any protection, unless one chose to call the spermatic cord and the delicate intercolumnar fascia such. It follows, therefore, that the logical procedure would be in direct hernia, to put our buttress to the mesial side of the deep epigastric artery, and in oblique hernia to the outer side of the deep epigastric artery.

Let us now turn to the final phase of the subject and see what we really accomplish in our operations for inguinal hernia. In order to fully comprehend this it will be necessary for me to draw a diagram of a finished hernia operation, of which Fig. 8 represents an operation with transplantation of the cord, and Fig. 9 one without any transplantation.

In all operations for inguinal hernia, as is well known, the internal oblique and transversalis muscles are sutured for a greater or lesser extent to Poupart's ligament. When the cord is transplanted, this line of attachment extends from the point of emergence of the spermatic cord, down to the spine of the pubis. (I omit as irrelevant all mention of the sutures, which are placed by some surgeons externally to the cord.) When the cord is not transplanted the line of attachment extends from the Poupartian origin of the internal oblique and transversalis muscles more or less to the spine of the pubis, but never quite to it, as an opening must be left to permit the escape of the spermatic cord into the scrotum.

Now note for a moment in Fig. 8 the site of exit of an indirect inguinal hernia. The hole in the transversalis fascia, through which the cord emerges, is seen. Assuming, for example, that a Bassini operation with transplantation of the cord

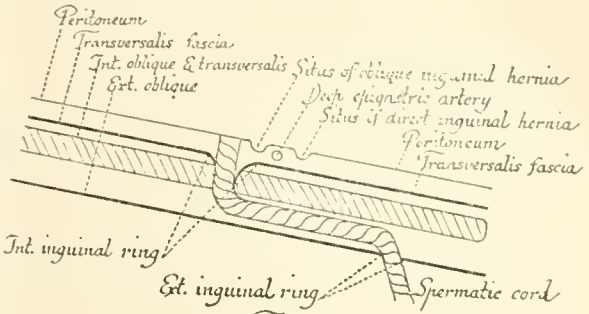

Fig. 8

is done; then the muscles are sutured to Poupart's ligament. But a hole is necessarily left for the exit of the cord. In other words, the hole in the transversalis fascia still remains, and we have accomplished merely an increase of the depth of this hole. This "hole" really represents a cylindrical hollow, very shallow when its wall is composed merely of the thickness of the transversalis fascia alone. By suturing the muscles to Poupart's ligament, this shallow section of a cylinder is deepened to the extent of the thickness of the muscles, but a literal closure of this "hole" or cylinder is not thereby accomplished. Over this opening is then sutured the aponeurosis of the external oblique; and, to my mind, this aponeurosis of the external oblique is the only structure that really occludes the hiatus. It is very apparent, however, that this operation very materially fortifies the canal to the mesial side of the deep epigastric artery. It follows, therefore, that this is evidently not the best operation for oblique inguinal hernia, but is the one of choice for direct inguinal hernia.

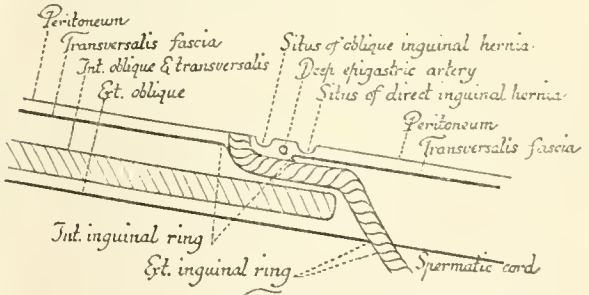

Fig. 9

Finally let us turn to Fig. 9. Again we see the hole in the transversalis fascia, through which the cord emerges. A Ferguson-Coley operation, without transplantation of the cord, is done. The cord is not disturbed, and over it the muscles are sutured to Poupart's ligament. Over that, as in all operations, the aponeurosis of the external oblique is sutured. It is true that in this case also, we have to leave an opening for the escape of the spermatic cord into the scrotum; but we have placed this opening downward and inward, at some distance from the internal inguinal ring, where it does not interfere with our buttress in front of the internal inguinal ring. Considering these points we must arrive at the conclusion that this is the operation of choice in oblique inguinal hernia and not in the direct variety.

I believe that if the rules I have offered be followed in practice, the percentage of recurrences after operations for inguinal hernia will be materially diminished.

Conclusions: 1. Oblique inguinal herniæ are to be operated upon without transplantation of the cord.

2. Direct inguinal herniæ are to be operated upon with transplantation of the cord.

925 Madison Avenue.

SCRUBBING ULCERS.

By ERIC CARL BECK, M.D.,

NEW YORK.

ATTENDING SURGEON TO ST. MARK'S HOSPITAL, INSTRUCTOR OF SURGERY AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL, CHIEF SURGEON AT THE GERMAN POLIKLINIK, ETC.

The varicose ulcer is the form of ulcer that I shall have reference to in particular, but as there is no plausible reason why this form of treatment should not be just as successful in the vast majority of ulcers that come under our care, I think it would not be out of place to discuss the definition, the structure, and pathological changes of ulcers in general.

The following sentences are taken from Rose and Carless' Manual of Surgery. "Ulceration has been defined as the 'molecular or particulate death of a part,' by which is meant the disintegration of the superficial tissues, which liquefy and disappear, usually without any obvious slough. It differs from gangrene in that the latter term is used to denote the simultaneous loss of vitality of a considerable portion of tissue. The two processes are, however, often closely associated, in fact both signify tissue necrosis; in the former the dead particles are not always visible to the naked eye, whereas in the latter the necrotic portions, if superficial, can always be seen." I use this definition because it seems to me both the simplest and most complete, especially appealing through the stress it lays upon the tissue necrosis. I shall quote further from the same source, going into the different stages of the ulcer, as we must endeavor to force each ulcer to go through its normal stages of development to healing and repair.

Stage 1: Ulceration proper, or extension. "The stage in which destructive changes are still continuing, and may be described as inflamed, spreading or sloughing ulcers. Naked-eye appearance: Surface covered with ashy gray or dirty yellow material, partly slough, partly lymph, partly breaking-down tissue; no granulations are present; the tendency to slough is most marked when the organisms are particularly virulent, or if the resistance of the tissues is much diminished; discharge considerable in amount, thin, sanious and often irritating and offensive, rarely purulent; margins thickened and inflamed, and the surrounding tissues often edematous and infiltrated; edge sharply cut and well defined; the base of the ulcer is thickened and fixed to the underlying structures. Stage 2: Transition period. The stage of preparation for healing. Naked-eye appearance: When the destructive process has ceased and the septic element has been eliminated, the surface of the ulcer begins to clean, and becomes, as it were, glazed over; sloughs and portions of dead tissue are either removed in the dressing or absorbed by the vitality of the leucocytes and fibroblasts. The discharge becomes less abundant and more serous in character, and the angry red blush is replaced by a rosy hyperemia. The infiltration of the base also diminishes, so that the tissues around are less fixed and more supple. The film on the surface becomes more and more defined, and in the course of time, shorter or longer, according to circumstance, little red spots make their appearance here and there; these gradually increase in number and size, and coalesce, until the whole surface is covered by what has now become granulation tissue. The processes occurring in this stage are: (a) the removal of the sloughs; (b) the covering of the surface with a cellulo-plastic exudation; (c) the vascularization of this newly formed material, and its conversion into granulation tissue. The varicose ulcer, which comes under the heading of this stage, occurs in the leg of a patient who is the subject of aggravated varicose veins. The skin becomes passively congested, and its nutrition is consequently impaired; any injury or abrasion which would readily heal in a sound limb is likely under such circumstances to give rise to a chronic sore."

It is of these chronic sores, or varicose ulcers that I wish to speak. I do not think that I make the percentage too high if I say that almost 40 per cent. of the cases we treat in our surgical clinics are varicose ulcers of the leg in their various stages of development. And what a bother they are as a rule! I remember how, in the *Königliche Chirurgische Universitäts Klinik* of Berlin, I and my fellow assistants drew lots, and the unfortunate loser spent all the morning cleansing and dressing varicose ulcers. Since that time it has ever been a trial during the treatment of these cases to find some other method that would cause a decided revolution in the stages of healing, some form of treatment that would overcome the sluggishness, the impassive course of the affliction. I believe that every physician who takes a personal interest in his clinic cases has also lost patience during their treatment, and has tried the countless ointments and moist applications that have been suggested. The latest one on the market is scarlet red, and it must be admitted that it does far more good in these cases than anything else of its kind. It is also valuable in treating burns. But in ulcers where we have a rather free discharge, its stimulating qualities do not go into effect until the ulcer has cleansed itself, and is well on the road to repair.

The definition of the second or transitional stage, given above, distinctly says, "sloughs and dead portions of tissue are either removed in the dressing or absorbed by the activity of the leucocytes and fibroblasts." And there we have the keynote, Nature's command, for the rational treatment: If we have a necrosis of bone, or osteomyelitis, we take out the necrotic pieces; the focus is removed, and repair begins. The tendency is there, in the process going on in these ulcers, but it is not quite powerful enough of itself and cries for outside assistance. So we help it along by a thorough cleansing, by "scrubbing" the ulcer with soap and water.

The patient is placed on the operating-table and deeply anesthetized. All crusts surrounding the ulcer or on any other portion of the leg are removed. An ordinary stiff brush, such as is used by the operator and his assistants for cleansing the hands before operation, is to be thoroughly sterilized. Tincture of green soap and sterile water is all that is necessary. The soap is poured on the ulcer, just enough water to cause a froth, and the scrubbing may begin. At first diseased and spongy tissue comes off in a dark black or grayish mass. A little clean water now and then will wash off the débris and show us

how far we have succeeded. Scrubbing should be continued until the base of the ulcer is smooth and the edges stand out clearly, red and hard, giving the whole the appearance of being "punched out." There will be some bleeding, but the bleeding seems to be conducive to quick healing. Strenuous scrubbing of the edges is necessary; it smooths them off sufficiently, and the hyperemia resulting therefrom will show its beneficial results within twenty-four hours, when the little blue line of infant granulations will bring its glad tidings of healthy recovery.

Before applying a wet dressing of either boric acid or bichloride solution, I paint the entire ulcer and its immediate vicinity with tincture of iodine to prevent reinfection as much as possible. As a rule when the patient regains consciousness she will complain of extreme pain, and if thought advisable some form of hypnotic may be administered. But if the bandage is kept moist with warm solution the pain and burning are only of short duration.

This method of scrubbing has been employed by several German surgeons who have used it to stimulate sluggish healing in unhealthy wound surfaces, and it seems to me that this form of mechanical stimulation promises a very large field of activity. The last case I treated in this vigorous manner presented a chronic ulcer of 16 months' duration, situated about two inches above the ankle-joint and approximately the size of a silver dollar. The woman was stout and 61 years of age. After the scrubbing, which was done very thoroughly, she remained in bed for four days, and then was treated by me in the dispensary of St. Mark's Hospital. After three weeks the entire ulcer had healed over completely with a thick, smooth, white scar. Granulation sets in at many different places and the repair is so quick and so ideal in its consummation that I am sure it can easily be called the perfect treatment of varicose ulcers of the leg. The only difficulty lies in the unwillingness of the average patient to be operated upon for a little thing like an ulcer.

AN AUTOMATIC DEVICE FOR READING SYSTOLIC AND DIASTOLIC BLOOD PRESSURES.

By B. RAYMOND HOOBLER, M.D.,

NEW YORK.

INSTRUCTOR IN CLINICAL PHYSIOLOGY CORNELL UNIVERSITY MEDICAL COLLEGE.

During the past few years many different forms of instruments have been devised for recording blood-pressures. With few exceptions these instruments depend upon pressure over the radial artery to determine pulse obliteration. Thus there is introduced into the blood-pressure reading of all instruments requiring tactile pressure over the radial artery to determine systolic pressure, what may be termed the personal element. With careful observers this may result in very small variations. However, different readers set for themselves different degrees of tactile sensation; some will read the pressure upon receiving the first sensation of a pulse wave even though other pulse waves do not come through; others demand that they shall feel all the pulse waves under the finger tips. Again different amounts of pressure with the finger over the radial artery will give various readings. Or a very slight movement of the muscles of the arm or hand of the patient may cause sensations similar to the reappearing of the pulse wave. In the tips of one's own fingers when the pressure is firm over the radial, there are often felt pulse beats which may become confused with the first faint pulse wave in the patient's artery. And, furthermore, all these difficulties are magnified when blood-pressures are taken in little children.

These chances of error are entirely eliminated and blood-pressure readings standardized through the use of the "double cuff" arrangement in connection with the Fedde pith-ball device. The principle on which it operates is a simple one. A cuff, such as is ordinarily used on any blood-pressure instrument, is placed about the upper arm of the patient. (A. Fig. 1.) This cuff is connected with

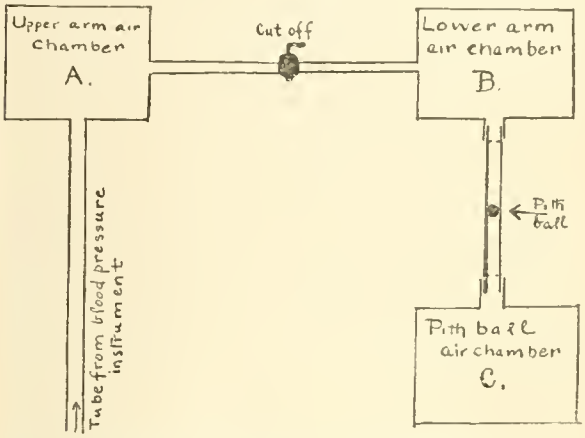

Diagram showing the air-chambers in the "double-cuff" arrangement for reading systolic and diastolic blood-pressures.

a much smaller one about the lower arm (B. Fig. 1) by means of a rubber tube in which is inserted a cut-off valve. (D. Fig. 1.) Also, from the lower cuff a rubber tube connection leads into another air-tight chamber (C. Fig. 1) which consists, for example, of a small rubber bag. Into this rubber tube connecting the lower arm cuff (B) with this rubber bag (C) is inserted a small glass tube (E) open at either end into whose bore is introduced a small pith ball after the manner devised by Fedde and described by him in the Medical Record of July 16, 1910.

From this description it will be noted that there are in the system three air-tight rubber bags connected with one another, viz., the rubber bag in the upper arm cuff (A), the rubber bag in the lower arm cuff (B), and the third one (C), which for convenience may be attached to the outside of the lower arm cuff.

In order to operate, the cut-off between the upper and lower arm-cuff is opened and air is pumped in as in filling the ordinary upper arm-cuff of any instrument. Instead, however, of filling the upper arm-cuff only, the air is passed into the lower arm-cuff as well as into the extra bag leading from it. The air is passed in continuously until the pressure in all the bags is about 100 mm.* mercury, as shown by the blood-pressure instrument. At this point the cut-off between the upper arm-cuff and the lower arm-cuff is closed, making now two distinct air-tight chambers, the one in the upper cuff (A) and the other made up of the rubber bag in the lower arm-cuff (B) and the bag connected with it (C). The two last mentioned bags are connected by the pith-ball tube (E).

*The exact pressure for most accurate reading is now being worked out and will be reported later.

As pulsations pass into the forearm there is at each pulsation slight enlargement of the volume of the forearm. Each enlargement will cause the air to pass from the bag in the cuff about the lower arm, through the tube containing the pith ball, into the rubber bag connected with it. This will force the pith ball to move in the direction of the air current, hence with each arterial pulsation air will rush from the lower arm-bag, causing the pith ball to jump. On the other hand, after each pulsation the arm will return to its smaller size, thus in obedience to the law of equalization of pressure, the air is made to flow back into the lower arm-bag, thus drawing the pith ball back toward the arm. Hence there are oscillations of the pith ball as long as there are arterial pulsations in the forearm. Now, if additional air is pumped into the upper arm-cuff, which is shut off from the lower arm-bag by the cut-off valve, to the point of obliterating the forearm pulsations, there will likewise be a cessation of the oscillations of the pith ball. At this point the height of the mercury column is read for the systolic pressure. Or, the air may be pumped into the upper cuff far above the true blood-pressure and allowed to escape through a needle valve. By this method, as soon as the pulsations appear in the forearm, they are recorded by the instant oscillations of the pith ball, this being the systolic reading. These results are identical whether taken at the cessation of the pith-ball oscillations or at the first appearance of such oscillations.

If the operator now opens the shut-off between the upper and lower arm bags and watches the oscillations of the pith ball as the air is permitted to escape through a needle valve, the point at which the oscillations are greatest is the place at which the diastolic pressure is read, according to the method devised by Fedde and referred to above.

This double cuff arrangement is particularly suited for taking blood-pressures in children. Instead of using the arm, which is often too small for the ordinary cuffs, one may apply it to the leg, placing what has been described as the upper arm-cuff about the thigh and the lower arm-cuff about the calf of the leg. The child does not object so much, and when the cuffs are once applied the child may be covered up, permitting blood-pressures to be taken out of doors as well as indoors, without exposure.

This lower arm or leg cuff can be attached to the cuff already in use on any blood-pressure instrument and does not necessitate a new outfit or a cumbersome addition to the one already possessed. This additional cuff, when carefully rolled up, measures 2 inches in diameter by 5 inches long, and in carrying can be placed inside the regular cuff, occupying practically but little additional space in the outfit.

What is more convenient, however, is that the two cuffs be combined into one cuff by suitable fastenings so that it may be used upon the upper arm if in adult or if used for children may be separated, one portion fitting below the knee or elbow and the other above either of those parts. It will be seen, therefore, that the only change that is necessary in adapting this improvement to any blood-pressure instrument is to substitute this new cuff for the old one.

Summary.—1. By means of this additional cuff systolic blood-pressure may be accurately read without the use of the fingers, thus eliminating all personal error and standardizing all blood-pressure readings.

2. Diastolic pressure readings are made with the same ease and accuracy.

3. The cuff may be attached to any outfit now owned whether aneroid or mercurial in type.

4. It is extremely simple and takes up but little space.

5. It may be used on the legs of children, thus overcoming the difficulty of small arms.

131 East Sixty-Seventh Street.

CONFIRMATION STUDIES OF WEINSTEIN'S TEST FOR CANCER OF THE STOMACH.

By LEONARD K. HIRSHBERG, M.D.,

BALTIMORE, MD.

Ever since the Neubauer and Fischer method of diagnosing cancer of the stomach was displaced by the plain tryptophan test, first evolved by Dr. J. W. Weinstein of the Vanderbilt Clinic in New York, I have been employing this simple method upon every case of uncertain gastrointestinal disturbance, particularly of the subacute or chronic variety.

Weinstein and Warfield have finally proved to our satisfaction that glycyltryptophan is not necessary for the demonstration of the Emerson enzyme—the peptidolytic enzyme present in cancer cells that digests proteins beyond the albumose through the amino-acid stage—and may be of no value, because of saliva that is swallowed. If the alkaline mouth juices are mixed with a faintly acid stomach content, tryptophan is produced from glycyltryptophan, thus vitiating the test.

In the early fall of 1910 Weinstein announced that tryptophan was one of the amino-acids always formed in the stomach if cancer was present. He showed that all of the common food proteins, such as egg albumin, casein, yield tryptophan by enzymolysis. Therefore it is unprofitable to waste time with the discredited Neubauer-Fischer method.

In an admittedly brief, yet painstaking experience, the older tests for cancer of the stomach, such as occult blood, hemolysis, present of lactic and absence of hydrochloric acids, and other newer methods, like Oppler-Boas bacilli, miostagmin, and Solomon tests, have proved decidedly less reliable than Weinstein's procedure. It is in my hands employed as follows:

A test meal, consisting of a glass of milk, a piece of white bread buttered with granulated sugar, or a piece of zwieback, an egg, and a glass of water; is extracted in one hour and a half. This is filtered, and immediately examined for tryptophan, thus: Six (6) c.c. of the filtrate in the test tube is mixed with four drops of 3 per cent. acetic acid solution. Four drops of a saturated watery solution of bromine are carefully added with a pipette. A reddish-violet color indicates the presence of tryptophan. If the rosy red color does not appear, allow it to stand twenty minutes. Should it not appear then, more bromine water, drop by drop, must be cautiously added. Excess of bromine will show as a yellowish tint.

If the procedure as thus far followed is uncertain or negative, the remaining stomach contents (both unfiltered and filtered) are placed in an incubator for one or two days. Antiseptics need not be added, for the microorganisms form no tryptophan. If then the examination shows no tryptophan, it does not necessarily prove the absence of

carcinoma. If, on the other hand, it is positive, cancer may be considered to be present.

Mrs. E. O. Physical examination negative. Weight stationary at 190 pounds. Fell from a step-ladder three months ago. Has lost her appetite since, but no weight lost. Is now constipated, except when taking purgatives. Was never so before. Five examinations made on alternate mornings gave positive tryptophan tests. An exploratory examination made by Dr. George DeHoff, her physician, showed an inoperable scirrhous carcinoma of the pylorus. The patient learned accidentally of the diagnosis and left the city for her mother's home in the West. This patient is 39 years old.

Twenty-one other patients with various gastro-intestinal symptoms, any one of which might possibly occur in carcinoma of the stomach, yielded negative test meals.

One other patient, B. H., aged 57, with a family history of carcinoma, has given so far seven negative results for tryptophan in tests extending over an interval of three weeks. The other signs, such as tumor, loss in weight, anorexia, occult blood in the gastric contents, and free lactic acid, seem to point positively to cancer. The patient refuses operation, although advised unanimously by her consultants to submit to one.

A NEW TYPHOID FEVER TEST.

(PRELIMINARY REPORT.)

By FRANCIS A. PRENDERGAST, M.D.,

BROOKLYN, N. Y.

ADJUNCT ASSISTANT PHYSICIAN, KINGS COUNTY HOSPITAL.

In the following report I desire to bring to the attention of the profession a new means of making an early and sure test for the presence of typhoid fever.

The test consists in injecting with a fine hypodermic needle a few drops of a suspension of dead typhoid bacilli of the strength of less than 5,000,000 per c.c. This strength may be easily made by taking the ordinary typhoid vaccine now on the market and diluting it as follows: Take one drop of the 1,000 million vaccine and add it to 20 drops of sterile saline solution. Mix thoroughly.

After the solution has been injected intradermally (care always being taken to raise as superficial a bleb as possible and with a well-mixed solution) in 24 hours the *non-typhoid* patient shows a well-marked area of redness around the point of injection. The typhoid patient shows absolutely no reaction. The reaction (as a rule) begins to appear in 12 hours, reaches its maximum in 24 hours, and has disappeared in 48 hours. Any redness after 48 hours is considered an infection and is not taken as a reaction. The test should be repeated with better precautions against infection. Rub the skin at the point of injection with alcohol, have a clean hypodermic syringe and needle, and use fresh sterile vaccine.

This test gives no constitutional reaction (rise of temperature, malaise, chill, etc.), and has no elements of danger. In the negative cases (controls) a few patients have complained of slight soreness and itching at point of injection 12 to 24 hours after the injection was given. This quickly subsided without treatment and gave no after trouble.

The following cases show the results as obtained on patients found in the wards of the Kings County Hospital. No attempt has been made to select them.

	ACUTE TYPHOID FEVER				NON-TYPHOID (CONTROLS)			
	No Reaction, Test Positive	Reaction, Test Negative	Widal		No Reaction, Test Positive	Reaction, Test Negative	Widal	
Case 1	Yes	. . .	Present	Case 13		marked redness	Absent	
Case 2	Yes	. .	Present	Case 14	Yes	. .	Present	
Case 3	Yes	. . .	Present	Case 15	Yes	. . . .	Absent	
Case 4	Yes	. .	Present	Case 16	. .	Yes		
Case 5	Yes	. .	Present	Case 17		Yes		
Case 6	Yes	. .	Present	Case 18	.	Yes		No Widal Taken
Case 7	. . .	Slight redness	Absent	Case 19	. . .	Yes		
Case 8	Yes	. . . .	Present	Case 20		Yes		
Case 9	Yes	. . . .	Present	Case 21	. .	Yes		
Case 10	Yes	. . . .	Present	Case 22	. . .	Yes		
Case 11	Yes	. . .	Present	Case 23	. .	Yes		
Case 12	Yes	. . .	Present	Case 24	. . .	Yes		
.	. . . .		. . .	Case 25		Good reaction	Absent	
. .	. .	. . .	. . .	Case 26	. .	Yes	Absent	
. .	. . . .	. . . .	. . .	Case 27	Yes	. . . .	Present	

Remarks: Case 7 ran a typical typhoid course, had several hemorrhages. The Widal test was made several times—always negative.

The patients used as controls suffered from such diseases as tuberculosis, chronic nephritis, chronic myocarditis, senile dementia, chronic rheumatism, acute bronchitis, etc.

Case 13 gave a history of typhus fever 40 years ago; very intense reaction. No treatment. No after trouble.

Case 14 gave history of typhoid fever 6 years ago.

Case 15 gave no history of typhoid fever. Unable to explain findings. Faulty technique.

Case 25 gave history of typhoid fever 3 years previous.

Case 26 gave history of typhoid-pneumonia several years ago.

Case 27 gave no history of typhoid fever. Urine not examined for bacilli.

Advantages of the Test.—No danger to patient. No danger from live culture (as in the Widal test).

No constitutional or local after-effect.

No microscope, no blood of patient, required.

Appears early—one case (case 6) 3 days before the Widal. How early future cases and a greater number will show.

Simple and easy to apply. No wait for laboratory report.

Seems to establish the diagnosis of typhoid fever even after the lapse of years, as exemplified in cases 14 and 25.

340 CLINTON STREET.

The Slight Nutritive Needs of the Cholera Vibrio.—M. Pergola has made various experiments to ascertain how much nutritive pabulum is necessary for the proper nutrition and multiplication of the cholera vibrio. For these experiments he made use of solutions of sodium chloride, ordinary potable water, distilled water, sea water, fecal broths, alkaline blood serum, and solid substances. He concludes that one must take great care in all epidemics of cholera not only to disinfect the stools and other excreta of the patient, but one must see that all fecal remains of healthy persons are disinfected, for it is found that a slight fecal mixture is all that is needed to cause a flourishing growth of the vibrio in any soil or water.—*Il Policlinico.*

MEDICAL RECORD.

New York, December 30, 1911.

MODEL QUARANTINE ADMINISTRATION.

THE enemies of Dr. Doty and those who want his place, either for themselves or for a personal or political friend, are untiring in their attacks upon his administration of the New York quarantine service. The investigator appointed by Governor Dix exhausted all the possibilities of unfair denunciation in his official report, and the others can only paraphrase the charges made by him, but they know the force of iteration and evidently believe that by constant repetition they can turn public opinion against the abused Health Officer. It makes no difference to them, of course, that Mr. Bulger's charges have been refuted, the refutation being supported, as his *ex parte* charges were not, by facts and figures open to the Governor or to anyone who cares to spend a half hour in their examination. Much capital is made, for instance, of the statement that three days after the "shocking disclosure" that little children suffering from pneumonia were treated by fresh air instead of being kept in rooms with doors and windows hermetically sealed, the children's hospital was discontinued, the patients thereafter being treated at the Ellis Island hospital. The fact was that the hospitals at quarantine were needed for the detention of cholera suspects; the cholera patients could not be sent to Ellis Island, but the children could be sent there, and so they were, in order to make room for patients or "contacts" who were of necessity detained at quarantine. Expert accountants were employed to search the records, and their report proves without question that the financial administration of quarantine was as correct as that of any business house in the country. These findings are ignored by the accusers of Dr. Doty, who prefer to accept the testimony of discharged employees and disgruntled immigrants.

It is a waste of time to repeat the refutation of all these charges in detail, but it is not without interest and may be of use to see what has been accomplished by way of betterment at the quarantine station under Dr. Doty's administration. When he was placed in charge of the station in 1895, there were less than twenty men employed in the Department; there are now one hundred and thirty-five persons employed in carrying out the various details of the work. These persons have been selected with reference solely to fitness for the particular service required of them, and the Health Officer is of necessity compelled to depend upon them in carrying out his orders. If any failed in their duty they have been called to a strict account and have been discharged if their dereliction was serious. No more than this can be expected of any administrator; even Mr. Bulger would hardly recommend himself for dismissal solely on the ground that his cook was found to have given a pork chop to her favorite policeman. At the beginning of his service Dr. Doty inaugurated a precise system of bookkeeping and accounting in connection with the financial affairs of the office; this system has been maintained, and the recent investigation by expert accountants shows that it has been effectual in safeguarding the funds of the State and in furnishing a permanent record of every important transaction of the office.

Prior to June, 1909, Hoffman and Swinburne Islands were under the jurisdiction of the Quarantine Commissioners, the powers of the Health Officer being limited in matters pertaining to general supervision, equipment, etc. At that date the Quarantine Commission was abolished and the Health Officer was placed in control of these islands. Urgently needed repairs and improvements were at once begun and wards were provided for the care of patients suffering from contagious diseases, making it possible to remove from incoming vessels all cases of infectious disease, thus avoiding unnecessary detention of the vessels, to the evident benefit of commerce. The needed improvements have not been made as rapidly as the Health Officer desired, for the reason that his time and that of his subordinates was absorbed night and day in dealing with two visitations of cholera, brought by incoming vessels. How successfully these visitations have been met is evidenced by the calm confidence of the community last summer as compared with the alarm felt when the *Normannia* brought a few cases to port twenty years ago. Although, for the reason just mentioned, there is yet much to do, nevertheless both Hoffman and Swinburne Islands are now fairly well equipped to deal with the work ordinarily required of them. At present Hoffman Island can care for upward of 1,500 suspects held for observation, being divided into three parts, so far as isolation is concerned, each part having everything that goes with scientific segregation—dormitories, large spaces for exercise, sanitary equipment, as well as ample kitchen and dining arrangements.

Swinburne Island is fully equipped to deal with the work required of it, including apparatus for the disinfection of stools and other discharges by boiling water. There are accommodations here for nearly one hundred patients, one ward having eight separate apartments for the isolation of suspects held for observation; two, and sometimes three medical officers are in constant attendance here, and there are also from six to ten trained nurses. The water supply on both islands has been greatly improved. one of the islands having a plant distilling four thousand gallons of sea-water a day, thus supplying a water free from all possible infection. At the

Boarding Station the bacteriological laboratory has been greatly enlarged; in place of one bacteriologist on duty there is now a permanent force of five or six. Not only is the ordinary bacteriological work carried on in connection with the diagnosis of cases on incoming vessels, but a large amount of original work has been accomplished in the investigation of steam, formaldehyde, sulphur dioxide, ozone, etc., to determine their germicidal value, and the results of this work have been made public for the benefit of quarantine officers and sanitarians in general. The disinfecting arrangements at Hoffman Island consist of three large apparatuses for steam disinfection, constituting probably the largest disinfecting plant in the world.

Did space permit, many more details might be given of Dr. Doty's faithful and scientific administration which has made the New York quarantine station a model that is being studied and imitated by sanitarians the world over. Enough, however, has been said to demonstrate the remarkable efficiency of the Health Officer in the difficult and responsible task of safeguarding New York and the entire country from imported epidemics of fatal disease. Not only the public health but the business interests of the country demand that this work be continued and perfected by the man who has brought it to its present condition. Medical men know, as no others can, the danger of entrusting this work, not yet completed, to inexperienced and possibly incompetent hands, and the medical profession of New York is practically unanimous in urging that Dr. Doty be reappointed, especially at this time, for it may be regarded as quite certain that within a very few months cholera will again be knocking at our door. Woe to the man who fails to recognize that knock and in his ignorance or incompetence opens wide the portal!

THE REWRITING OF MEDICAL HISTORY.

So far is the history of disease and medical practice from being a really closed chapter that one would almost be warranted in stating that it is yet in its beginnings. New histories of medicine continue to appear, along with new journals devoted to medical history. An increasingly large number of representative medical men are becoming interested in historical episodical research. New documents come to light, not only in writing but in all other aspects of archeology. New and improved translations of old texts are made, and new interpretations are continually supplied, as suggested and illuminated by modern discoveries. As a matter of fact this movement, if continued sufficiently, would mean an exhaustive rewriting of medical history.

The vigor of this tendency cannot be better illustrated than in the mixed reception given to Bloch's demonstration that syphilis must henceforth be regarded as purely an American disease and that syphilis could not have existed in (old world) antiquity. While the majority of well-informed readers owned themselves convinced by Bloch's arguments, not a few new documents to the contrary have since come to life, prominent among which is an apparently unassailable manuscript showing that an Italian expression corresponding to "French disease" was current before Columbus was born.

The Division for the History of Medicine and the Sciences in the Congress of German Naturalists and Physicians, together with the Archives which form the official publication of this section, is doing much for this work of revision. At the recent annual meeting of this body (*Münchener medizinische Wochenschrift,* November 14) Richter gave evidence to show that anthrax—splenic fever—must be more reckoned with in dealing with ancient epidemiology. This should be true of all plagues of animal origin, for we have knowledge enough that such diseases prevailed unheeded in old civilizations ignorant of hygiene. We have every reason to believe that most if not all of the diseases originating in animals or having a strong incidence therein were prevalent in remote epochs when men shared their houses with all the domestic animals and not with dogs and cats alone, to a degree hardly conceivable to-day.

Bubonic plague is now known to be a disease primarily of certain rodents. The plague of old Athens has recently been compared with modern typhus because both diseases claim dogs as co-victims with men. Richter seeks to prove that much so-called erysipelas in ancient and medieval times was the disease which we now commonly associate with cattle and sheep, and term variously "anthrax," "splenic fever," "splenic edema," "wool-sorters' disease," etc. The same writer, dissatisfied with the old translations of the great Arabic-writing physicians of the tenth and eleventh centuries made by Constantinus Africanus and Stephanus, has recently caused new ones to be made and finds numerous misconceptions in the older renderings. He believes that our knowledge of the beginnings of smallpox may be carried back several centuries beyond the period of first recognition heretofore assumed. It would appear that, so far from having been derived originally from India and China, variola was first heard of among the Christianized Ethiopians and entered Arabia from Africa before the time of Mahomet. The Arabians spread it to the Persians and these perhaps to the more Eastern and Southern Asiatic peoples.

The thirteen years which have expired since the creation of this scientific body have certainly been so prolific of results as to justify renewed extension of the movement in the future. This movement is now represented by organized effort in France, Germany, and Italy; while the well known Dutch periodical, *Janus,* devoted for years to the history of medicine, will in the future be published in French under the designation *Archives internationales pour l'histoire de la médecine et la geographie médicale.* It is, of course, comprehended fully that a movement of this sort is not inferentially committed to any sensational overturning of the older history. It simply regards all matter of historical significance, however trivial it may seem, as worthy of the most careful study. New interpretations and new criticism become inevitable, and in turn stimulate renewed interest.

The Lenhartz Dietetic Treatment.

This remedial procedure, which has been tested by its sponsor and others upon a very large material which comprises every type of underfed patient, is said to differ chiefly from the Weir-Mitchell and other examples of forced alimentation, first, in relative limitation of fluids, and second, in a harmonious increase of all three basic classes of nutriment; finally, the number of meals is not increased over that demanded by custom. The regimen differs to some extent from some of the older plans in being suited to subjects who are able to take voluntary exercise in the open air, and this exercise is part of the regimen. Bed rest is often required at the outset, and during this period massage and passive motion are practised. With disappearance of exhaustion and irritability an active existence is begun. Sleep is secured by hydrotherapy; regular bowels by diet and enemata, together with massage. The only drugs used are bismuth for hyperacidity, and iron and arsenic for anemia. At a recent meeting of the Hamburg Aerztlicher Verein (*Muenchener medizinische Wochenschrift*, November 7) Kissling reported the results of the regimen in several hundred cases. In four to six weeks the average weight gain was seven or eight kilos, and in six to eight weeks ten kilos. The regimen is particularly suited to nervous dyspeptics. In discussion Schottmüller stated that many rebelled against the cure, and that vomiting and diarrhea were set up with loss of weight. Hirschstein appeared inclined to credit some of the benefits attained to the large dosage of sulphur derived from the increased amounts of meat, eggs, and milk consumed. The good results in neurotics attributed to increased nitrogen could be explained more rationally in this manner. Nonne thought the benefit was best explained by suggestion. Brauer attached importance to the development of culinary resources, which is a phase of hospitalism as yet hardly essayed. Each hospital should have special diet catering for the underfed.

The Seriousness of Measles.

Physicians in this and other countries are beginning to regard measles in its true light, that of a disease serious in its menace to health and life. Reports recently of the death rate from measles have revealed the fact that it is by no means a disease to be treated lightly. When it attacks adults it generally leaves in its wake a train of dangerous sequelæ. Sir John F. H. Broadbent, writing in the *Practitioner* for October, draws attention to the lack of wisdom shown by medical men in Great Britain in allowing the old belief that measles was a trifling complaint to be perpetuated. It seems that it is not even a notifiable disease in London, and few, if any, measures are taken to hinder the spread of infection. That it is acutely infectious in the catarrhal stage is well known, but on account of the ignorance of parents it is seldom that attempts are made to carry into effect the lesson to be learned from this fact. Dr. Sykes, medical officer of health for St. Pancras, goes so far as to recommend that inasmuch as the mortality from measles is mainly among children under five years of age, and infection is spread chiefly through the convergence of a large number of children to different centers, such as schools, all children under five years of age should be permanently excluded from the elementary schools. The great mortality that not infrequently accompanies an epidemic of measles, for example the mortality in the recent epidemic in London, is invariably due to neglect of precautions in the early stages of the disease.

Function of Cell Oxidases.

Intracellular oxidation has recently been studied through color reactions as observed under the microscope, this method constituting a check on the older one of investigating the enzyme properties of tissue juices and extracts. The color method is well adapted to the study of leucocytes, and in fact furnishes us with a new resource for counting the latter in any tissue section or in any fluid. In localities like the appendix, for example, it becomes possible to determine the degree of inflammation present. But if the new method be a criterion for the existence of oxidases in tissues our knowledge of the latter will have to be recast, for it has recently been asserted that with the exception of the salivary and lacrymal glands no color reaction has been obtained that would not be accounted for by the presence of the leucocytes in the tissues. The color method has therefore been investigated thoroughly by von Gierke (*Muenchener medizinische Wochenschrift*, October 31), who devised new technical resources and was able to produce color reactions in the various cells which differed from that given by leucocytes. Muscle substance, as might have been expected, gave a pronounced reaction, the colored granules appearing in the sarcoplasm; and doubtless all cells which perform active functions show some reaction, although the author could obtain none from the glomeruli of the kidneys. It is not claimed that the reaction throws much light on the intimate nature of cell metabolism. At most it shows that cell oxidation receives a new demonstration which is unlike any other in that it is concerned with the cell as an individual. The nature of the color reaction is such that it could occur only in the presence of certain oxidizing substances and enzymes.

The Department of Insurance Medicine.

When, with the beginning of the present volume of the Medical Record, a department of insurance medicine was established, it was largely in the nature of an experiment. While the physician engaged in insurance work is, and from the nature of his work must be, interested in general medicine and all its branches, there are nevertheless certain problems and facts which bear more particularly upon his special calling, and it is to his advantage to have these topics grouped in a special place where they can be found readily without searching through the fifty or more pages in each issue of the journal. It was because we believed that the thousands of examiners and medical officers of insurance companies would appreciate this effort to meet their wants that we established the department, but only a trial would prove whether or no this belief was well founded. It is a pleasure now to state that the many letters of commendation received from individuals and the formal endorsement given to the project by associations of medical directors and examiners have convinced us of the acceptability of this feature, and we can therefore promise that the page or more of Insurance Medicine will be continued as one of the regular departments in each issue of the Medical Record during the coming year.

News of the Week.

Dr. Charles H. Mayo of Rochester, Minn., has had the unpleasant experience of submitting to two abdominal operations within a week. On Friday, December 15, on his arrival in this city from Washington, where he had been at the annual meeting of the Southern Surgical Association, he was seized with abdominal symptoms suggesting both appendicitis and cholecystitis. An operation was performed the following evening and a gangrenous appendix was removed. On the next Friday he was taken with unmistakable symptoms of cholecystitis and was operated on again Saturday, when a number of gallstones were removed. Both operations were successful and the welcome report comes from the Presbyterian Hospital, where the patient lies, that he is convalescing satisfactorily. The operator both times was Dr. Joseph A. Blake.

The Typhoid Epidemic in Trenton.—During the second week of December 16 new cases of typhoid fever were reported to the Health Board of Trenton, making a total of nearly two hundred cases in the past two months. The water supply has been given the hypochlorite treatment and the people are claiming that it is undrinkable.

School Inspection in Bridgeport.—At the monthly meeting of the Health Board of Bridgeport, Conn., the report read showed that during November 1,773 pupils in the public schools had been inspected and that of this number 635 were found physically defective and 22 mentally defective. A free clinic has recently been established in this city for the treatment of school children and a number of dentists have given their services, without charge, to children whose parents were unable to pay.

Pellagra in Mississippi Town.—The town of Meriden, Miss., has just commenced to keep a record of vital statistics and the report for the month of November caused considerable surprise in that 27 cases of pellagra were recorded, there being more than twice as many cases of pellagra reported as of any other disease.

Insanity Increases in New Jersey.—The annual report of Dr. Britton D. Evans, Medical Director of the State Hospital for the Insane at Morris Plains, says that, while he has room in his institution for only 1,600 patients, he has to care for 2,245, and that a similar condition is reported at the State Hospital in Trenton. The ratio of increase in the number of patients over previous years is startling. There have been only 188 deaths, or 7 per cent. of those under treatment, while the number of patients discharged as cured or improved has been 25 per cent. of the number admittted. It is pointed out that New Jersey has no hospital for the criminal insane.

Pennsylvania State Vaccination Commission.—Governor Tener has appointed the following members of the State Vaccination Commission, all of Philadelphia: Dr. Wm. H. Welch, Dr. Jay F. Schamberg, ex-Governor Samuel W. Pennypacker, George Wharton Pepper, Emil Rosenberger, Porter F. Cope, and John Pitcairn. The law provides that two members of the board shall be pro-vaccinationists and two anti-vaccinationists. The duties of the Commission are to examine into the history, nature, and pathology of smallpox; the means to be employed for diminishing the prevalence of and the mortality from the disease; the history, nature, and pathology of vaccination; the original sources from which the various strains of vaccine virus now in use have been obtained. Study is to be made further of the mode of preparation of virus used for vaccination and of other matters pertaining to smallpox and its treatment. The Commission is to make a report to the Legislature on or before February 1, 1913.

Smallpox Spreads in Pawtuxet Valley.—The epidemic of smallpox which has been raging in Pawtuxet Valley, R. I., has spread until the victims now number several hundred cases. Several cases have appeared in the vicinity of Brown University and all of the students have been compelled to submit to vaccination.

Public School Children Must be Vaccinated.—Owing to a smallpox scare in Maspeth, the Health Department and the Board of Education have ordered all children in the public schools of Queens who have not been vaccinated within two years to submit to that operation.

English Physician's Oppose Lloyd-George's Insurance Scheme.—A mass meeting of over 2,000 doctors from all parts of the United Kingdom met in London on December 19 for the purpose of protesting against the Lloyd-George insurance plan. They hissed Sir Victor Horsley and members of the Council of the British Medical Association, which they charge with having sacrificed the interests of the profession. Sir Victor Horsley was denounced as a traitor when he tried to defend the action of the Council in promising Mr. Lloyd-George that the doctors of the United Kingdom would do their share toward the success of his measure. Resolutions were passed in favor of boycotting the scheme and refusing to treat the poor under its provisions until the demands of the medical profession were granted. The local insurance committees are now left to provide medical attendance and to pay the doctors, and the British Medical Association has asked that 10 per cent. of the committeemen shall be doctors. They claim that it is impossible to bring the resources of modern medical science within the reach of all at the estimate of the Chancellor of the Exchequer of six shillings per head. It has been foreseen that some of the poorer members of the profession may suffer by the stand taken and be tempted to accept conditions which will be degrading to themselves and a detriment to the public, and the National Medical Union has formed a plan to raise a fund of $2,500,000 from which to make grants to physicians who refuse to treat beneficiaries under the law. Six thousand doctors are already pledged not to accept service under the act.

Pasteurization of Milk Compulsory After January 1.—The resolution of the New York Board of Health adopted as an amendment to the Sanitary Code requiring that after December 31, 1911, all milk and cream offered for sale in the city, except that used for manufacturing and cooking purposes, must be of the grades designated and recognized by the Board of Health as "certified" or "guaranteed" milk, or it must be pasteurized under the conditions prescribed by the regulations of the Board of Health, has been slightly modified. There has been a change in the subdivision of grades which will permit the great bulk of milk used in manufacturing and in bakeries to go through without stringent precautions. Neither the corner groceryman nor the local dairyman will be able to get

any milk of this grade. The grade to be known as inspected milk will be practically the same as the certified milk, except that the cattle have not necessarily been subjected to the tuberculin test. With the exception of the certified and inspected milk the bulk of milk sold to small consumers will be pasteurized at a temperature of from 150° to 160° F. for twenty minutes. It is claimed that nothing like this system has been put into effect in any other city in the world, and that it is so thorough in its application that the consumer will have the assurance that every quart of milk bought is pure.

Would Make Use of Antitoxin in Diphtheria Compulsory.—The Scott County Medical Society recently met at Davenport, Ia., for the purpose of adopting resolutions asking the State Board of Medical Examiners to revoke the license of a practitioner who failed to use antitoxin in two cases of diphtheria, which resulted fatally. The resolutions denounced the failure to use antitoxin in a case of diphtheria as a crime against the patient and against the community.

To Prosecute Unlicensed Physicians.—The State Board of Health of Illinois announced that it is preparing to prosecute graduates of medical colleges and others who are practising medicine without a license. Notification was sent to Chicago Hospitals some time ago calling the attention of hospital authorities to the fact that graduates in medicine should not be allowed to practise in hospitals under the guise of assistants unless licensed and that this warning has been disregarded.

New York Hospitals Overcrowded.—The Department of Charities reports that New York's facilities for caring for its sick poor are still inadequate. The city hospitals are overcrowded and thousands are being turned away who are in need of treatment. It is believed, however, that the hospitals now under construction on Blackwells Island, in Flatbush, and on Staten Island will help toward the solution of the problem.

New Hospital for Ontario.—The new general and marine hospital erected in St. Catherines, Ontario, was opened on November 24 by Lieut.-Governor Gibson. This hospital is said to be the best equipped hospital in Ontario; it was built at a cost of $75,000 and can accommodate 50 patients. The old hospital will be renovated and used for any overflow that may occur.

Hookworm Dispensaries in North Carolina.—It is announced that free dispensaries for the treatment of hookworm will be established in Hanover County, N. C., by the Board of County Commissioners acting in conjunction with the State Board of Health. In Pender County 5,000 persons were examined; in Columbus County, 6,000, and in Onslow County, over 7,000; and it was found that from 60 to 75 per cent. of this number were infected with the hookworm.

The Ninth Congress of American Physicians and Surgeons.—At the first meeting for organization of this Congress, held in this city on December 23, the following officers were elected: *President of the Congress*, Colonel William C. Gorgas, U. S. Army; *Chairman of the Executive Committee*, Dr. William H. Carmalt, New Haven, Conn.; *Treasurer of the Congress*, Dr. Newton M. Shaffer, New York; *Secretary of the Congress*, Dr. Walter Ralph Steiner, Hartford, Conn.: *Secretary of the Executive Committee*, Dr. William Kelly Simpson, New York. The Congress will meet in Washington, D. C., in May, 1913.

The Canadian Public Health Association held its first congress in the new medical building of McGill University on December 13, 14, and 15 under the presidency of Dr. T. A. Starkey. The first session was held in the Convocation Hall of the Royal Victoria College when His Royal Highness, the Duke of Connaught, Governor-General of Canada, made the opening address. Many cabinet ministers and premiers have lent their names to the association and Canada's High Commissioner sent a check of $2,500 to be used as they pleased. The Hon. Martin Burrell, Minister of Agriculture, said that he believed that the time had come when, if public health did not need a portfolio, it should at least have a full-fledged department in the Federal Government. The meeting was a success in every particular.

The Surgical Association of the Chicago and Northwestern Railway, which held its fifth annual session in Chicago on December 14, elected the following officers: *President,* Dr. H. M. Workman of Tracy, Minn.; *Vice-Presidents,* Dr. A. L. Wright of Carrol, Ia., and Dr. R. B. Bowen of Maquoketa, Ia.; *Secretary and Treasurer,* Dr. J. D. Andrews of Chicago.

The Southern California Medical Society, which held its forty-fifth semi-annual meeting in San Diego, Cal., on December 7, elected the following officers: *President,* Dr. Stanley F. Black of Pasadena; *Vice-Presidents,* Dr. T. A. Stoddard of Santa Barbara, and Dr. Robert L. Doig of San Diego; *Secretary and Treasurer,* Dr. John A. Colliver of Los Angeles.

The Clinical Society of the Mountainside Hospital was organized at Montclair, N. J., on December 4, 1911, and elected the following officers: *President,* Dr. Richard P. Francis; *Vice-President,* Dr. William H. Areson; *Secretary and Treasurer,* Dr. Stella S. Bradford.

Professor Odilon Marc Lannelongue, one of the leading surgeons of Paris, died on December 22. He was born in 1840, received his medical degree in 1867, and was appointed professor of surgery at the University of Paris in 1884.

Dr. Emil Altman was tendered a dinner by the Executive Committee of the Eastern Medical Society at the Café Boulevard on December 15. Among those present were Dr. Graeme M. Hammond, Dr. Louis K. Neff, Dr. L. J. Ladinski, Dr. Frederic Bierhoff, and Dr. S. J. Kopetsky.

Dr. Peter K. Olitsky has been appointed Assistant Adjunct to the Gynecological Department of the Har Moriah Hospital, New York City.

Removal.—Dr. W. E. Bullard has removed from Palm Beach, Fla., to Larchmont, N. Y.

Dr. James J. Walsh, Professor of Medical History in Fordham University, has been appointed medical editor of the New York *Herald.*

Montclair Wins Milk Fight.—After resisting that section of the Sanitary Code of the Montclair Health Board for four years requiring the tuberculin test for the herds from which the local milk supply is obtained, it has been announced that the Borden Condensed Milk Company has decided to submit to the ordinance. The ordinance requires that tuberculin tests be made of all cows from which the Montclair milk supply is obtained and that charts showing the results of the test be filed. The

veterinarian's certificate must also contain a statement as to the number of cows in the herd that are free from disease of any kind.

Charitable Bequests.—By the will of the late J. Henry Cochran of Williamsport, Pa., the sum of $10,000 is bequeathed to the Williamsport Hospital.

The will of Sarah A. Teller, who left a large estate in the Bronx, gives the residuary estate to Lebanon Hospital.

The Far Eastern Association of Tropical Medicine will hold its second Biennial Congress at Hong Kong from January 20 to 27, 1912. Papers will be classified so as to give, if possible, a day to each of the following groups: I. Protozoology, Helminthology. II. Cholera, Plague, Leprosy, and Tuberculosis. III. Tropical fevers, including Malaria, Beriberi, and Dysentery. IV. Surgery, Obstetrics, and Infantile Diseases. V. Climate, Hygiene, and Sanitation. Medical men in the Far East willing to introduce subjects for discussion should communicate at once with the secretary, Dr. Francis Clark, Hong Kong. Papers may be read in English, French, or German, but a brief abstract in English should be sent in.

Obituary Notes.—Dr. Andrew Benedict Ward of New York City, a graduate of the College of Physicians and Surgeons in 1896, member of the American Medical Association, the Medical Society of the State of New York, the Harlem Medical, Clinical Assistant, Department of Pediatrics, Vanderbilt Clinic, died at his home December 16, aged 39 years.

Dr. William F. Millington died at his home in Brooklyn on December 15. He was graduated from the New York University Medical School in 1877 and served three years in the Marine Hospital Service. He was 57 years of age.

Dr. Robert C. Lindsey of Moultrie, Ga., a graduate of the Atlanta College of Physicians and Surgeons in 1900, died suddenly on December 7 at the age of 37 years.

Dr. J. W. Warner of Miami, Fla., died at his home December 8.

Dr. J. C. Egan, who was during the Civil War chief surgeon in charge of the Confederate military hospitals, died at his home at Mount Lebanon, La., December 9.

Dr. Elizabeth Henderson Lang McClure died at Philadelphia on December 12. She was graduated from the University of Boston School of Medicine in the class of 1877. She was a member of the Homeopathic Medical Society of the County of Philadelphia, of the Pennsylvania State Homeopathic Medical Society, and of the American Institute of Homeopathy.

Dr. Summerfield R. Bond of Baltimore, a graduate of the University of Maryland in 1883, died of pneumonia at his home in Baltimore on December 21 at the age of 48 years. He was the chief medical examiner of the Relief Department of the Baltimore & Ohio Railroad.

Dr. Milton Robert Bailey of Peoria, Ill., a graduate of the Western Reserve University Medical College, Cleveland, Ohio, in 1882, died at his home November 22, aged 56 years.

Dr. William R. Page of Washington, D. C., died at his home November 26. He was a Civil War veteran and for many years practised medicine in Washington.

Dr. George Leroy Rice of North Adams, Mass., a graduate of George Washington University, Department of Medicine, Washington, D. C., in 1862, died at his home November 28 at the age of 73 years.

Dr. Pierre George Dausch of Baltimore, Md., a graduate of the University School of Medicine, Baltimore, Md., in 1868, died at his home November 26. He was 65 years old.

Dr. Joseph Bassett Trudgian, a graduate of the George Washington University in 1887, died suddenly at his home in Washington, D. C., on November 26. He was born in 1856 and served as a surgeon in the Spanish-American War.

Dr. John Wagner, who had been practising medicine in San Francsico for forty years, died suddenly in that city on November 22. He was born in Ohio, and graduated from Cooper Medical College, San Francisco, in 1872.

Dr. John T. H. Slayter, formerly a military surgeon in the Philippines, and later a resident of Helena, Mont., died at his home in Watertown, Mass., after a long illness, on November 24. He was a graduate of the College of Physicians and Surgeons, New York City.

Dr. Albion S. Whitmore died at the Deaconess Hospital in Boston on December 1. He was born in 1851, graduated from Bowdoin College in 1875, and from the Columbia Medical School at New York in 1878.

Dr. E. S. McClellan of Saranac Lake died at the home of his daughter in Northampton, Mass., December 2, at the age of 87. For twelve years he was president of the Saranac Lake Board of Health and compiler of a Sanitary Code for the prevention of tuberculosis.

Dr. James Sumner Greene died from pneumonia at his home in Dorchester Lower Mills, Mass., on December 15, at the age of 77 years. He was graduated from Harvard Medical School in 1863 and was a Civil War veteran.

Dr. Peter David Hughes of Kansas City, Kan., died of cancer of the stomach on December 11. He was born in 1855, graduated from the College of Medicine at Fort Wayne, Ind., in 1884. He was chief of the surgical staff of Bethany Hospital, Kansas City, Kan., and president of the Northeast Kansas Medical Association in 1905-1906.

Dr. John W. Thorp died of pneumonia on December 15 at his home in Oxford, N. Y. He was born in 1839 and was graduated from the University of New York, Medical Department, in 1871.

Dr. La Fayette Rinkle of Boonville, N. Y., a graduate of the Long Island Hospital Medical College in 1874, was paid a well-deserved tribute by members of the Oneida County Medical Society. He died December 6.

Dr. J. E. MacNeill of Denver, Col., a graduate of Northwestern University Medical School, Chicago, in 1878, died in Waukesha, Wis., December 3.

Dr. William D. Collins of Cambridge, Mass., a graduate of Harvard Medical College, 1866, died December 16 at the age of 71.

Dr. Fabius J. Haywood, who graduated in medicine in 1868 from Bellevue Hospital Medical College, New York City, died suddenly at his home in Raleigh, N. C., December 14, at the age of 71 years.

Dr. William A. Moore, a graduate of Memphis Medical College in 1888, died at his home in Quit-

man, La., December 13. He was 45 years of age.

Dr. C. J. C. Ficher of Carlinville, Ill., a graduate of Washington University, Medical Department, St. Louis, in 1877, died at his home December 15. He was 57 years old.

Dr. Patrick H. McMahon, a graduate of the University of Vermont in 1894, died suddenly at his home in Burlington, Vt., on December 14 at the age of 57.

Dr. James C. Egan of Shreveport, La., died at the home of his daughter, Mrs. A. J. Colbert, in Mt. Lebanon, on December 15 at the age of 89. He was graduated from the New York University Medical School in 1846, was chief surgeon of the military hospitals in Louisiana during the last two years of the Civil War, and for a time vice-president of the State Board of Health, and also of the State Board of Medical Examiners.

Dr. Dennis P. Wims, a graduate of Dartmouth Medical College in 1897, died of pneumonia at the Rhode Island Hospital, Providence, on December 8.

Dr. John W. Flatley died of pneumonia at his home in Philadelphia on December 12 at the age of 30 years. He was graduated from Jefferson Medical College in the class of 1903.

Dr. Henry K. Hartzell, a retired physician, died of pneumonia at his home in Allentown, Pa., on December 20. He was a graduate of Jefferson Medical College and of the University of Vermont.

Dr. J. Gaunt Edwards of Williamstown, N. J., died of heart disease on December 22 at the age of 63. He was graduated from Jefferson Medical College in 1878 and was formerly coroner of Gloucester County.

Dr. Rhett Goode died of Bright's disease at his home in Mobile, Ala., on December 22 at the age of 58 years. He was graduated from the Medical College of Alabama, Mobile, in 1871, was president of the American Railway Surgeons' Association, and dean of the medical department of the University of Alabama.

Obituary.

JOSEPH EDWARD JANVRIN, M.D.,

NEW YORK.

Dr. Joseph E. Janvrin died at the Roosevelt Hospital on December 20 following an operation for appendicitis performed some days previously. He was born in Exeter, N. H., on January 13, 1839, and received his degree from the College of Physicians and Surgeons in this city in 1864, after having served through the Civil War as assistant surgeon of the Fifteenth Regiment, New Hampshire Volunteers. His war record earned him membership in the Union League Club and the Loyal Legion, of which he was an active member. From 1872 to 1882 he served as assistant surgeon to the Woman's Hospital of the State of New York. Since 1883 he was consulting gynecologist to the New York Skin and Cancer Hospital. His contributions to his specialty speedily won him a high position in the profession. Dr. Janvrin was one of the founders of the International Congress of Gynecologists. He was president of the American Gynecological Society in 1902 and 1903, and president of the New York Obstetrical Society in 1890 and 1891. He had previously been president of the New York County Medical Society in 1896 and 1897.

Dr. Janvrin is survived by his widow, a daughter, and a son, Dr. Edmund R. P. Janvrin.

Correspondence.

AUTOBIOGRAPHY OF A CASE OF ANEURYSM OF THE INNOMINATE ARTERY.

To the Editor of the Medical Record:

Sir:—The fact that it is almost universally conceded that an aneurysm of any large intrathoracic vessel is practically always fatal prompts me to report the history of my own case to awaken interest in a new method of cure first suggested by Dr. Albert Abrams of San Francisco, in his work on Spondylotherapy. Dr. Abrams has reported in the *British Medical Journal* of July 8, 1911, and in *La Presse Médicale* of Oct. 4, 1911, forty cases of aneurysm of the thoracic and abdominal aorta that were symptomatically cured after a few weeks' treatment by his method of concussion. Some of these patients were seen four years after their discharge with no recurrence of symptoms.

The history of my own case is as follows: Age 80 years; practised medicine continuously for 47 years, during 8 years of which time I was A. A. Surgeon in the U. S. Army. Had influenza in 1888, and since this time have suffered from cardiac arrhythmia. During the last 5 years I have experienced almost constant coldness and numbness in my left leg. About one year ago pains of a peculiar sickening and prostrating character were experienced in the arms and chest; they would awaken me at night, when I felt as if somebody were pressing with all his might and main on my chest. About three months ago I felt a pressure on my trachea which affected my voice to the extent of aphonia. Since about one year I first observed a diffused pulsation of the suprasternal fossa. My symptoms increasing in severity, I was examined by Drs. Gallagher, Brown, Callan, and Fleming of El Paso, all of whom concurred in the diagnosis of an aneurysm.

I then decided to go to Dr. Abrams for treatment. An examination by Dr. Abrams revealed a dilatation of the arch of the aorta, but the arteria innominata was chiefly implicated in the angiectasis. After my very first treatment a troublesome and persistent cough disappeared and has never returned. At the commencement of treatment my voice, which was then only a "squeak," was rapidly restored to normal. After twelve treatments I observed the following relative to my condition: cardiac arrhythmia disappeared, coldness and numbness in my left leg are no longer present, the pressure on my trachea and the air-hunger have disappeared. In fact, I regard myself as absolutely well. At about the end of a week the suprasternal pulsation was reduced fully 50 per cent.

The following, which bears on the subject of this article, is interesting. For some time I had noted that after riding in my automobile at home there was a development of an intense paroxysm of dyspnea, but this was not observed after riding in large autos. In directing the attention of Dr. Abrams to this fact, he explained it as follows: While concussion of the seventh cervical spine will produce contraction of the aorta by the elicitation of the aortic reflex of contraction, concussion of the third dorsal spine will dilate the aorta by elicitation of the aortic reflex of dilatation. In riding in my car the position of the third dorsal spine corresponded to the back of my seat, and there is no question in my mind that the paroxysmal dyspnea was evoked by the constant concussion of that particular part of my spinal column.

The disappearance of arrhythmia and other circulatory disturbances can be attributed to Dr. Abrams' method of myocardial-toning, inasmuch as his method for contracting the large blood-vessels is equally efficient in producing the heart reflex of contraction.

W. T. Baird, M.D.

El Paso, Tex.

OUR LONDON LETTER.

(From Our Regular Correspondent)

INSURANCE BILL SENT TO THE LORDS; SOME MEDICAL OPINIONS ON IT—HOSPITAL ASSOCIATION—GENERAL MEDICAL COUNCIL—BRITISH MEDICAL ASSOCIATION'S CIRCULARS AND THREAT, SECRETARY TO BE A COMMISSIONER—GASTRIC SECRETION, EXPERIMENTS WITH TEA, COFFEE, ETC.—INFECTIVE ENDOCARDITIS WITH RECOVERY—NORMAN KERR LECTURE—FOOT-AND-MOUTH DISEASE MICROBE—OBITUARY.

London, December 8, 1911.

The Insurance Bill has passed the Commons after a third reading remarkable for its acrimonious character. Mr. Lloyd George indulged in his most objectionable platform style, charged his opponents with being actuated by bad motives, and asserted that his own intentions were of the highest. He harped so much on this that the opposition leader responded sarcastically: "I know the road down which the Chancellor would lead the House is paved with the best intentions, but the beauty of the pavement does not alter the destination."

So the bill goes to the Lords with the blessings of the government and followed by protests of various interests besides the medical. Most curious is the revolt of the trade unions and labor party, who have actually addressed a petition to the House of Lords they did so much to destroy, and on whose support the government confidently counts. It looks like a huge political joke. But I must turn to medical opinions.

The Hospital Association has held a meeting at which 195 delegates of hospitals were present and reaffirmed the unanimous opinion previously passed, that the bill is incomplete unless it provides for hospital treatment of the insured, and, further, that this cannot be adequately maintained by voluntary contributions, as they will be diminished in consequence of the provisions of the bill. Sir H. Burdett, in an effective speech, said when they saw Mr. Lloyd George he told them the remedy was in their own hands; they had only to ask applicants, "Are you insured?" for, if so, they had no right to go to voluntary hospitals. So insured persons were ineligible. Sir Henry declared in that case the only alternative was State hospitals, which the Poor Law Commission said would cost twenty millions a year in addition to the twenty millions required to put this bill into operation.

The fear of hospital authorities provoked by the bill is further illustrated by the committee of the Maidstone Memorial to King Edward. At first they intended to endow a new wing to the West Hunt General Hospital with the £6,500 they have already raised. They have now passed a resolution that "in the event of the hospital or any of its trust funds or investments being taken over by the State, or any department of the State, the special fund shall immediately cease to be held for the benefit of the hospital, and shall be dealt with as may hereafter be decided by the committee or its successors." This is a plain indication of the mistrust entertained in many directions as to how far the example of confiscation set by this government may be followed.

Even the General Medical Council has been roused from its habitual torpor, and appointed a committee on this bill and adopted its report and submitted the same to the government. Fair words and some minor changes formed the response, but despite these the president was not satisfied as to the grave danger to voluntary hospitals, and suggested that if their fears were justified government should be asked to legislate to obviate the danger.

But by far the most active professional body has been the B. M. A., and that not only this week, but from the time the bill was proposed. Its managers have throughout insisted on the six points they first laid down, and though they have not gained them they have shown that other means can be employed. Circular has followed circular in rapid succession. The whole profession has been urged to support the six points and also to sign an undertaking not to accept any office under the bill except in accordance with these terms. As to this, the Council seems to be disappointed at the slight response, for another circular was issued yesterday to those who had not signed the form, reminding them of their neglect and, I am sorry to say, accompanied by a threat. Admitting that "probably no two members of the profession would agree upon identically the same policy," it goes on to say there will be no alternative but to regard those who refuse to commit themselves "as being, however unintentionally, enemies of the profession." I think that a most unjustifiable threat. Some call it a monstrous assumption as well as a contradiction in terms. Others talk of a strike and say the Association is learning the trade union methods of "intimidation of blacklegs." In the same envelope as this threat went a stiff request for a subscription toward the expenses.

Another development of the situation is also exciting some attention. The Medical Secretary of the Association, Mr. J. Smith Whitaker, has been appointed deputy-chairman of the "Insurance Commission" under the bill. Before accepting he referred the question to the Council of the Association, which held a special meeting. After discussion they recommended him to accept. Then they sent a circular to members "to make them aware of the reasons for this step," the principal one being that it provides a prospect that the "schemes and proposals of the Local Insurance Committees shall be considered by a competent expert in the interests of the medical profession."

Nevertheless many are discontented and a correspondence has been started in the *Times* and other papers, calling the consent of the Council "a shameful betrayal," and other choice things. Officials of the Metropolitan branch have replied, expressing inability to understand how the appointment can be so regarded, seeing Mr. Whitaker is a staunch supporter of the Association and its six points.

Drs. F. C. Moore and H. S. Allanson have communicated to the Medical Section (R.S.M.) some interesting observations on the human subject as to the varying effects of gastric secretion of tea, coffee, and other accessory foodstuffs. A test breakfast was given at 8 A.M. containing 10 ounces of water or other fluid at an agreeable temperature. One hour after the stomach contents were removed,

at once filtered, and in the filtrate the free HCl and the total acidity estimated; the peptic activity was also estimated. The results with a test breakfast of 10 ounces of water and four breakfast biscuits were used as the basis of comparison, the measure of the secreting activity being determined by an average of not less than three experiments in each case. The observations were made on fifteen individuals, including healthy subjects as well as some with gastric disorder. The results show that tea (infusion) induces greater secretion of gastric juice than water, the average in fourteen cases being with tea, HCl 53.2, total acidity 70.8, peptic activity 8.0, in place of 42.7, 62.2, and 6.7, respectively, with water. In the individual cases a similar, but varying, relation was found in all except two, in which the secretion was diminished. A solution of caffeine (3 grains in 10 ounces water) was used in a number of experiments on three individuals; in two it was more potent; in the third it was somewhat less than tea and weaker than water. The average of the total observations showed the watery solution of caffeine and infusion of tea were equally stimulating to the gastric secretion, but seemed to indicate that individual susceptibility is more pronounced with coffee than with tea. Cocoa showed some individual originality and took its place between water and tea as a stimulus of gastric secretion. The observations with milk in five out of six cases showed its stimulus was less than that of water. The authors suggest that this is due to the inhibitory action of its fat, and they attribute further to the splitting of this an excess of total acidity, though the HCl and pepsin were diminished. A watery infusion of a meat extract and albumin water both proved powerful stimulants of gastric secretion. Alcohol and tobacco-smoking, tried in two normal individuals, gave opposite results, probably dependent on individual susceptibility at the time.

At the Medical Society of London Dr. Walter Carr brought forward a case of recovery from infective endocarditis. A woman of twenty-six, who was confined in January and was suddenly attacked with right hemiplegia on February 28, was admitted to hospital March 10. She then had a systolic murmur at the apex and *Staphylococcus pyogenes* was found in the blood. She got steadily worse for five weeks, temperature being irregular (98° to 104°). Heart became greatly dilated, dullness from one inch to right of sternum to over one inch outside of left nipple line. Urine often contained blood and albumin, right kidney palpable and tender. Three injections were given of an autogenous vaccine without benefit. Antistaphylococcic serum was then injected six times in all—10 c.c. twice and then 15 c.c. After last injection temperature became normal and improvement followed. The patient left hospital June 30 in good health and doing full ordinary household work. Mitral regurgitation remains, and the only remnant of the hemiplegia is a slight weakness of the hand.

The Norman Kerr lecture this year was delivered on November 14 by Dr. Sims Woodhead, professor of pathology in the University of Cambridge, and he gave it in the theater of his department. Dr. Hyslop, president of the Society for the Study of Inebriety, which was founded by Dr. Kerr in 1884 and which now takes charge of the memorial lecture, occupied the chair. The subject taken by Professor Woodhead was the effect of alcohol on the heart and this he illustrated by tracings thrown on the screen. Among these were three pairs of curves from persons who had taken each ½ oz. of absolute alcohol. In each there was a rise of temperature in the axilla and a simultaneous fall in the rectum. When food was taken the reverse took place—a rise of visceral and fall of surface temperature. But when hot fluids were taken there was a sudden rise in both but not of long duration. Dr. Woodhead intimated his intention of carrying on his experiments on an extended scale.

Dr. Collingridge, the Medical Health Officer for the city, has resigned on account of failing health. He has worked for the city—and worked well, too—for just thirty years.

Dr. Siegel of Berlin claims to have discovered and cultivated the microbe of foot-and-mouth disease. To some extent he says immunity is conferred by inoculating the cattle with his microbe, which he has named cylorrhyctes and which he demonstrated at the Prussian Veterinary Congress on the 25th ult.

Surgeon-General Gerard James Irvine, R. N., died suddenly at Lucknow on November 18.

Dr. J. Wise Martin, consulting surgeon to the Jessop hospital for women at Sheffield and secretary of the Medical Society there, died after a long illness on November 23, the end coming rather suddenly of apoplexy. He had practised in Sheffield over thirty years and was highly esteemed by his colleagues. He had been lecturer on midwifery at the university and examiner under the midwifery board. He had also served in the Rifles, in which he attained the rank of Surgeon-Colonel.

Dr. F. W. Bond, M.O.H. of Gloucester, has died at the age of seventy-seven. For many years he has been one of our leading sanitarians. He qualified in 1856, taking an arts degree the same year in the London University, in which he proceeded to graduate in medicine, M.B. with the medal 1857, M.D. 1860. He became professor of chemistry at Queen's College, Birmingham, and afterwards of clinical medicine with the physiciancy to the Queen's Hospital. He translated Radicke's "Medical Statistics" for the new Sydenham Society and contributed to the journals and societies on medical subjects, as well as many reports on public health, officially and otherwise. He also founded the Jenner Society for the defence of vaccination, the practice of which he advocated with great effect.

Mr. H. R. Heather Bigg died on the seventh inst. in his fifty-eighth year. He took the double qualification at Edinburgh in 1884 and the Fellowship of the Surgical College there in 1888. He wrote several works on orthopedic subjects especially with regard to the mechanical treatment of deformities, also a report for the government on possible improvements in substitutes for lost limbs granted to soldiers.

An Outbreak of Tonsillitis or Septic Sore Throat in Eastern Massachusetts and Its Relation to an Infected Milk Supply. C.-E. A. Winslow.
Clinical Aspects of the Epidemic of Septic Sore Throat in Cambridge, May, 1911. E. A. Darling.
An Epidemic of Tonsillitis Due to Infected Milk. M. W. Richardson.
Observations on the Epidemic of Sore Throat Occurring in Boston and Vicinity During May, 1911. J. L. Goodale.
The Practical Application of Blood-Vessel Surgery. E. H. Risley.
Tuberculous Epididymitis: An Analysis of 153 Cases. J. D. Barney.

Septic Sore Throat in Eastern Massachusetts.—C.-E. A. Winslow presents an epidemiological study of an out-

break of this condition in Boston and its vicinity, during May, 1911. The cases occurred mostly in households supplied with milk from a certain dairy.

Clinical Aspects of Epidemic Sore Throat in Cambridge.—E. A. Darling states that about one thousand cases of this disease were observed in Cambridge during May, 1911. Nearly all occurred in well-to-do families living in the best residential parts of the city. The organisms found in the throat were streptococci, often associated with staphylococci or pneumococci. The most serious cases occurred in persons above the age of forty. The period of incubation was short, not more than thirty-six to seventy-two hours. The throat symptoms were those of follicular tonsillitis, or simulated those of diphtheria, and were accompanied by marked constitutional symptoms. Practically all except the mildest cases had more or less marked involvement of the cervical lymph-nodes. About one-quarter of the cases had complications of one kind or another. The most frequent complication was abscess formation in or near the throat. Other complications noted were acute arthritis, peritonitis, pleurisy, pneumonia, endocarditis, nephritis, and erythema. The complications were metastatic processes. There were twenty-seven deaths.

Epidemic Tonsillitis.—M. W. Richardson describes how the epidemic of tonsillitis which prevailed in eastern Massachusetts during May, 1911, was traced to a farm supplying milk to a certain dairy.

Epidemic Tonsillitis.—J. L. Goodale reports his experiences in twenty-six cases of this condition that came under his observation in Boston during May, 1911.

Blood-Vessel Surgery.—E. H. Risley states that uniformly successful blood-vessel sutures are not easily made, but by the persistent application of a careful technique, which has as its bases the utmost respect for the extremely delicate tissues dealt with, and a certain regular amount of laboratory work, reasonable success can be insured by any one doing general surgery.

Tuberculous Epididymitis.—J. D. Barney presents an analysis of 153 cases of this condition noted at the Massachusetts General Hospital.

Observations on the Influence of Ipecac upon Intestinal Amebiasis. D. Roberts.
Relation of Salvarsan to the Ear. S. Seegman.

Psychological Mechanism of Paranoia.—A. A. Brill reports the history of a case of paranoia which he analyzes with reference to Freud's conception of this disease. According to Freud, the paranoiac character lies in the fact that as a reaction to a defense against a homosexual wish-phantasy there results a delusion of persecution.

Hypertrophic Pulmonary Osteoarthropathy.—By H. Brooks. (See MEDICAL RECORD, December 16, 1911, page 1247.)

Ventral Suspension of the Uterus.—G. S. Foster describes a new operation that he has devised for ventrofixation of the uterus.

Hemolytic Tests in Blackwater Fever.—C. Wellman and C. C. Bass tested in a case of blackwater fever the following reactions: (1) complement fixation; (2) the hemolyzing effect on normal human corpuscles of serum from the patient ill with blackwater fever; (3) the hemolyzing effect of quinine sulphate on corpuscles from the patient ill with blackwater fever. The complement fixation reaction showed in most instances complete hemolysis. The other two reactions were negative.

New Reflex Sign in Typhoid Fever.—C. B. Burke describes this new sign as follows: The arm of the patient is bared to the shoulder. The thumb and middle finger of the examiner are arched in the shape of a horseshoe and placed over the biceps muscle of the arm, so that the arch thus formed is completely filled; then firm pressure is made by the finger and thumb, and the hand is briskly raised (pressure being continued) so that the thumb and finger come together with a slight concussion. The result, if the reflex is present, is a fibrillary contraction of that portion of the biceps muscle traversed by the thumb and finger, producing an oval ridge without complete contraction of the biceps muscle. The ridge thus formed disappears slowly. If the reflex described is absent, the author concludes that typhoid fever is not present. This sign is, however, found also in other diseases, which is also true of nearly all other signs. The absence of this reflex in diseases simulating typhoid fever may be of signal aid in arriving at a correct diagnosis. This reflex seems to be governed by the virulence of the infection.

Enteroptosis and Altered Function of the Diaphragm.—F. M. Pottenger calls attention to disturbances in the function of the diaphragm due to pathological conditions within the thorax. He emphasizes the fact that patients suffering from chronic diseases of the lungs and pleura often suffer from enteroptosis, not only because of wasting or a congenital enteroptotic habit, but because of the pathological conditions found above the diaphragm. This is especially true in all those conditions which result in a chronic cough and an emphysematous condition of the lungs. One finds this in so-called idiopathic emphysema; also in all compensatory emphysemata, such as those found as a result of asthma, mediastinal tumors, or chronic tuberculosis, especially when the active disease has been circumscribed at least for a considerable portion of time. In the latter case, as a result of prolonged coughing, those portions of the lungs which are not affected usually take upon themselves a chronic emphysema, and the lower borders are pushed down and often fill the entire pleural space, pushing the diaphragm and the underlying abdominal organs before them.

Diphtheria Antitoxin and Anaphylaxis.—J. A. Roddy states that a first injection of horse serum into man is innocuous; anaphylaxis is rarely manifest after a subsequent injection, and when it occurs complete recovery usually follows. The danger of anaphylaxis is insignificant in comparison with the danger of diphtheria. The necessity of administering a second dose of diphtheria antitoxin, and consequently the occurrence of anaphylactic phenomena can be almost, if not entirely, avoided by the proper administration of the first dose.

The Noguchi Reaction.—M. Lederer concludes that with a positive Noguchi reaction in the primary stage antisyphilitic treatment can be instituted early. In tertiary syphilis a positive reaction is often present and is of aid in diagnosis. So-called cured syphilitics should be examined for latent syphilis. Efficiency of and indication for further treatment can be guided by routine blood tests. As a prophylactic test in human hematological therapeutics and to those who have had syphilis and are contemplating marriage a serological test is of value.

Ipecac in Intestinal Amebiasis.—D. Roberts reports good results in the treatment of intestinal amebiasis by means of the administration of large doses of ipecac, which he regards as a specific in this condition. After preliminary catharsis, the patient takes forty grains of powdered ipecac in pills carefully prepared with successive coatings of salol and keratin. When the pills were properly coated, no nausea or emesis resulted, although the fact that they dissolved in the intestine was proved by the appearance

of methylene blue in the urine, which drug was included in the makeup of the pill. The stock pills were found to be useless. The ipecac in the forty grain dose was given, usually daily for five days. Preceding the ipecac by one-half hour, fifteen drops of tincture of opium, or a corresponding amount of powdered opium, were given. The opium was not always necessary to prevent nausea or emesis when properly coated pills had been used, but was exhibited rather to check the active catharsis brought about by the doses of ipecac. Ice compresses at the throat were found to be of comparatively little value. After five days of large doses the ipecac was reduced ten grains each day and the treatment was completed in eight days.

Salvarsan and the Ear.—S. Seegman concludes that in affections of the ear, no matter how slight, there is the danger of salvarsan intensifying the symptoms.

Supraclavicular Subcutaneous Lesions of the Brachial Plexus.—By C. H. Frazier and P. G. Skillern. (See MEDICAL RECORD, July 1, 1911, page 51.)

Cyclical Appearance of Pneumonia, Grip, and Enteritis.—By C. M. Richter. (See MEDICAL RECORD, July 1, 1911, page 46.)

Gunshot Wound of the Arm.—G. A. Skinner reports a case of wound in a boy aged 13, from a charge of shot which removed an extensive area of skin and superficial structures from the forearm, tore away the whole of the outer head and belly of the biceps in the upper arm and a portion of the lower end of the deltoid, and broke the humerus squarely across. The brachial artery was exposed uninjured. While the case looked hopeless as far as saving the arm was concerned, it was cleaned up, the patient was transfused with saline solution and conservative measures were decided on. Two days later the sloughing tissues were removed. There was a severe infection of the wound requiring daily dressings, and necrosis occurred at the broken ends of the humerus. A resection was made and a portion of calf's femur, duly prepared, was inserted and fixed with bone pegs. The fixation apparatus was arranged and the wounds began to heal, skin grafts being employed to make up the deficiencies. The torn ends of the biceps were united and filled up the wound with slight shortening of the arm. An unexpectedly good recovery was made.

Strangulated Appendix in a Femoral Hernia.—P. Oliver reports a case of this condition.

Habitual Epigastric Protrusion.—A. Bassler reports a case of this condition occurring in a boy aged seventeen years, and resulting from habit.

Albumin Milk.—J. M. Brady notes that in this preparation an effort is made to have the milk-sugar as low as possible, as this is regarded as the chief offending element, giving rise to fermentative changes in the bowels. Therefore, the whey which contains the lactose is removed as much as possible; the buttermilk which is added also contains a low lactose percentage. An average percentage of fat (2.50) is fed, as the fat itself only takes part secondarily in the acid fermentation, if the fermentation of the milk sugar has already begun. The high proteid diet counteracts fermentative changes caused by the feeding of a very high carbohydrate percentage. Clinical results seem to prove the incorrectness of the belief that high proteid feeding injures the organism by the excessive demand made on the metabolism of the infant, particularly the kidneys. It appears that the reason that one can cause a gain in weight so rapidly in these run-down infants is the fact that one can incorporate in the mixture such a large carbohydrate percentage, without causing an intoxication. The prevention of the development of the intoxication is due to the high percentage of proteid, and low percentage of lactose and mineral salts.

Multiple Neuritis with Twelfth Nerve Paralysis.—R. P. Smith reports a typical case of multiple neuritis with the unusual complication of paralysis of the twelfth nerve on both sides. About two months prior to the appearance of any symptoms the patient had been taken with an acute and severe pain in the ovarian region, necessitating the attendance of a physician, who found a well-defined excessively tender mass over the left ovary, with a rise of temperature ranging from 101 to 103° F., which disappeared in about three days, leaving only a local tenderness. A week or two previous she had been exposed to cold and damp, but this is not considered by the author as an efficient cause of the trouble, though it may have been to some extent a factor. He suggests that the mass found over the ovary may have been an ovarian cyst, the breaking down of which caused a toxemia and the paralysis observed.

Korsakoff's Psychosis.—A. W. Hoisholt reports three cases of this condition, which has been observed in connection with intoxications other than that of alcohol, in morphinism, etc., and after certain diseases such as erysipelas and certain brain tumors. It is difficult to definitely give a prognosis in cases in which the amnesic symptom-complex appears. An infectious etiology and one due to carbonic acid or arsenical poisoning may have a more favorable prognosis, but where the disease has developed in previously unhealthy brains following alcoholic excesses and in arteriosclerotic and senile cases the prognosis is not so good. Exercise of the recording faculty may lead to improvement in cases that are amenable to treatment.

Postoperative Cystitis.—By J. H. Jacobson and J. G. Keller. (See MEDICAL RECORD, July 8, 1911, page 103.)

Pericystitis.—By M. L. Harris. (See MEDICAL RECORD, July 8, 1911, page 103.)

Occupational Disease Reports.—By J. B. Andrews. (See page 1340.)

Pyelography.—By W. F. Braasch. (See MEDICAL RECORD, July 8, 1911, page 102.)

Tonsil-Pillar Divulsor.—L. R. Culbertson has devised this instrument for removing a submerged tonsil.

Cultures from the Thyroid.—J. J. Gilbride reports six cases of exophthalmic goiter and eight cases of cystic goiter, in which cultures were made from the gland. A growth of *Micrococcus tetragenus* was obtained in one case of exophthalmic goiter, and a growth of *Streptococcus vermiformis* of Sternberg was obtained in one case of cystic goiter. In none of the others was a growth obtained.

Hematoxylin Stain.—J. A. Johnston describes a method for the rapid preparation of this stain.

Sinus Punch.—W. P. Reaves describes a new instrument of this kind that he has devised.

Retrolabyrinthine Affections.—H. B. Graham states that Barany has shown that in intralabyrinthine affections the kinesthetic sense is not interfered with, while in the retrolabyrinthine affections involving the vestibulo-cerebellar tract there is a marked disorder in the motions of the body which accompany the nystagmus. One can diagnose affections of the vermis by the patient always falling in the same direction, no matter what the position of the head may be, and with disturbances of the cerebellar hemispheres the pointing movements of the arm or leg will aid in the diagnosis. The comparison of the caloric and galvanic tests on the two sides is also an aid in differentiation.

Hygiene of the Swimming Tank.—W. J. Lyster concludes that pathogenic organisms may readily find entrance to the water in swimming tanks by means other than the water-supply, and may possibly cause disease. There is a large increase in the number of organisms normal to any particular water, as well as of others, during the period that water is held in the tank. All of these organisms are quickly destroyed by small amounts of chlorine readily added to the water in the tank every morning before the usual hours of use. The accumulations of hair and other débris observable at the bottom of the tank should be removed daily by small hand pumps, these accumulations affording a favorable medium for the development of certain organisms and being less readily disinfected than the water. The hygiene of the tank is aided by the construction of troughs at the edges to afford places for expectoration and to prevent water draining back into the tank from the sides. A shower bath should be used before the swimmer enters the common tank.

Kindergarten Test Card.—W. Reber has devised a new visual test card to be used in estimating the vision of young children.

Postnasal Hemostat.—H. R. Boettcher has devised a self-retaining instrument for controlling bleeding from the postnasal space, especially following adenectomies. The instrument consists of a cannula 10 inches long, bent up to about a right angle at the small end, over which a small rubber bag is placed and fastened with a silk thread. To the large end of the cannula a rubber tube 6 inches in length, with air-bag attached, is fastened. The cannula has a stop-cock for the purpose of controlling the air.

New Forceps and Test Card.—F. Allport describes a strabismus forceps, an advancement forceps, and a new visual chart for schools.

Scalp Hemostat.—H. J. H. Hoeve has devised a scalp hemostat which fulfills the following requirements: It compresses the entire thickness of the scalp evenly at the incision with sufficient force to control all hemorrhage, but without bruising the tissues. When applied it is not in the way of the operator. It facilitates subsequent work on the skull, and the introduction of sutures.

Intrathoracic Tumors and Aneurysms in Their Clinical Aspect. G. Steell.
Some Early Signs and Symptoms in Nervous Disease. J. Taylor.
Venereal Disease: Its Present and Future. D. White and C. H. Melville.
Treatment of Graves' Disease with the Milk of Thyroidless Goats. W. Edmunds.
Enuresis and Thyroid Extract. A. C. D. Firth.
The Use of Rosenbach Tuberculin in Surgical Tuberculosis. F. J. Rosenbach.

Intrathoracic Tumors and Aneurysms.—G. Steell states that pain is seldom altogether absent in the course of intrathoracic tumors. Aneurysmal tumors are the more productive of pain, the frequency, intensity, and persistency of which are also greater. The pain is either referred or due to direct pressure on somatic nerves or on bone. Another important symptom is dyspnea. As regards the pulmonary changes, it is noted that preceding the development of dullness there is an increase of resonance caused by overdistention of the lung from interference with the escape of air. The dullness resulting from intrathoracic neoplasms and aneurysms may be caused by pulmonary collapse, "retention pneumonia," dilatation of the bronchial tubes, fibroid thickening of the lung, secondary infections resulting in breaking down of the lung, gangrene, or pleurisy and empyema. Paresis or paralysis of a vocal cord is more common than it is generally believed to be. The cervical sympathetic nerves may be implicated, causing changes in the pupil and palpebral fissure and in the secretion of sweat. There may be affection of the brachial plexus, causing weakness and sensory disturbance of the arm. There may be paraplegia, dysphagia, hemoptysis, hematemesis, and cutaneous hemorrhage. Inspection of the chest may show bulging, the presence of distended veins, immobility, and retraction of one side of the chest, and the "tracheal tug." On palpation one may note that the entire heart is thrust forward by the pulsations of an aneurysm of the descending portion of the aortic arch. A diastolic shock is felt over a superficial aneurysmal sac. It represents the closure of the semilunar valve. A difference in the two radial pulses is a familiar sign of aortic aneurysm. The most valuable auscultatory sign of aortic aneurysm is accentuation of the second aortic sound, though murmurs are very common.

Early Signs and Symptoms of Nervous Disease.—J. Taylor notes the difficulty frequently experienced in differentiating between an organic and a functional disease of the nervous system. He cites the case of a young girl who had difficulty in walking quickly. This was due to a slight toe-drop on one side. Examination showed a marked ankle-clonus on this side and a distinct extensor response from each sole. In a few months the characteristics of disseminated sclerosis developed. In patients complaining of difficulty in walking one should bear in mind the possibility of spinal caries with pressure myelitis. In subacute combined sclerosis an early sign may be a peculiarity in walking which resembles somewhat the walk in tabes. Gastric crises may be an early sign of tabes. In acute visual disseminated sclerosis loss of vision may be the first sign. Cases of tachycardia with a history of wasting, severe attacks of diarrhea and considerable cardiac and abdominal discomfort justify a diagnosis of Graves' disease.

Venereal Disease.—D. White and C. H. Melville note that the annual toll to venereal diseases in the United Kingdom amounts to half a million of infected individuals.

Treatment of Graves' Disease with the Milk of Thyroidless Goats.—W. Edmunds reports six cases in addition to the thirteen which he has previously reported showing the good results obtained by this treatment.

Thyroid Extract in Enuresis.—A. C. D. Firth reports a series of sixteen cases of enuresis in which thyroid extract was administered. Two of the cases were cured and 60 per cent. showed marked improvement. The initial dose was one-quarter or one-half grain daily.

The Use of Rosenbach Tuberculin in Surgical Tuberculosis.—F. J. Rosenbach states that a study of the biochemical reciprocal effects of bacteria and plants led him to submit a culture of tubercle bacilli to the action of a trichophyton. From this resulted the preparation of a new tuberculin, in which the poisonous constituents are destroyed and the immunizing constituents preserved. This tuberculin is used in two ways: the first is by means of subcutaneous introduction into the circulation for the treatment of inaccessible local tuberculosis. The second method of administration is by means of direct injection into the diseased foci—*e. g.* joints, tendon sheaths, lupus, etc. In this case the tuberculin produces the same process, but much more intensely. The author reports favorable results in the treatment of forty-seven cases.

The Surgery of the Abdominal Wall. Sir A. P. Gould.
Certain Operative Procedures in the Paralysis of Children. With Special Reference to Poliomyelitis. R. Jones.
Neurotic Dyspepsia. G. Rankin.
Radium in Malignant Disease and Varicose Ulceration. T. Ross Macdonald.
A Case of Rodent Ulcer Presenting Some Unusual Features. R. Farrant.
The Bacteriology of the Cockroach. C. C. Morrell.

The Surgery of the Abdominal Wall.—Sir. A. P. Gould states that the first points to be determined in any operation on the abdominal contents are the position and the extent of the incision. The incision should be, whenever possible and as much as possible, directly over the organ or lesion which has to be dealt with internally. One should always think of the abdominal wall as one of the most important muscles of the body, and remember that the aim of the surgeon in operating through the abdominal wall should be to make such a wound as will not injuriously interfere with this muscular apparatus or will interfere with it as little as possible. Upon the integrity of the linea alba, therefore, depends the perfect function of the whole of the abdominal wall. Anything which weakens the linea alba is liable to cause much more apparent and more serious mischief than that which weakens other parts of the abdominal wall. In renal surgery, it is well in exposing the kidney not to make a transverse cut regardless of the direction of the fibers of the muscles in the loin. The incision should be oblique, and made parallel with the fibers of the external oblique muscle, and the surgeon should separate the fibers of this muscle, and should be careful not to cut the twelfth dorsal nerve.

Operative Procedures in the Paralysis of Children.—R. Jones discusses this subject with special reference to the deformities of poliomyelitis.

Neurotic Dyspepsia.—G. Rankin notes that the function of any organ can be disturbed only in one of three ways—by excess, by default, or by perversion. According to this proposition he accepts Robin's classification of dyspepsia under three primary headings, according as it is caused by hyperfunction, hypofunction, or abnormal fermentations. Neurotic dyspepsia is frequently mistaken for duodenal ulcer, and differentiation is not always possible.

Radium in Cancer and Varicose Ulcers.—T. Ross Macdonald states that in many cases the maximum benefit is to be obtained only by the use of relatively large amounts and by the application of these over relatively prolonged periods of time. In reference to the amount of radium employed, the author generally uses tubes containing 250 to 300 milligrams of pure radium bromide. The initial expense is enormous, this quantity of pure radium bromide being worth nearly $25,000, but, if inoperable malignant disease can be cured or even greatly relieved, the gain manifestly counterbalances the outlay. With regard to filtration and dose, the author uses tubes containing 250 milligrams of pure radium bromide, which, for deep-seated cancers, he screens with 2½ millimeters of platinum, leaving them in position from twenty-four to forty-eight hours. When possible, and with the assistance of a surgeon, he inserts the tubes with the same filtration into the tumors for forty-eight hours. He also tries to get cross rays by applying tubes above and beneath the growths, which methods have so far given the best results. For superficial lesions he has used the radium unscreened for half an hour, repeated every other day for a week.

Rodent Ulcer.—R. Farrant reports an unusual case of this condition in a man aged 62 years. There were three ulcers. One appeared on the lip fifteen years ago and healed spontaneously. Another ulcer had appeared shortly before this time on the face and remained stationary ever since. Nearly two years ago a boil in the inguinal region existed for six weeks and then ulcerated, forming a typical rodent ulcer.

Bacteriology of the Cockroach.—C. C. Morrell reports the following results of his experiments: The common cockroach is able by contamination with its feces to bring about the souring of milk, to infect food and milk with intestinal bacilli, to transmit the tubercle bacillus, to disseminate pathogenic staphylococci, and to transmit from place to place destructive moulds. These facts, taken in conjunction with the life-habits of the insect, lead to the conclusion that the cockroach is able to, and may possibly, play a small part in the dissemination of tuberculosis and in the transmission of pyogenic organisms; that the insect is in all probability an active agent in the souring of milk kept in kitchens and larders; and that it is undoubtedly a very important factor in the distribution of moulds to food, especially when it is kept in dark cupboards and cellars where cockroaches abound.

December 4, 1911.

Nature of Paget's Disease of the Nipple.—Kreibich decides that this affection cannot be conceived anatomically as an eczema which becomes carcinomatous. The inflated cell which is typical of this affection may be shown to be a melanoblast in which ordinarily the formation of pigment has ceased. Exceptionally it persists, and occurs with the development of non-pigmented malignant tumors in pigment nevi. The so-called Paget cell tumor is not necessarily confined to the nipple. We are therefore forced to conclude that the Paget cell is an anaplastic melanoblast in which the lipoid function is for the most part retained while the pigmentation is very largely abolished. Paget's disease represents a superficial melanoblastoma which stands in definite relationship to deep melanoblastoma (formerly known as melanosarcoma). The author would always extirpate these growths with the knife.

Pregnancy and Cardiac Disease.—Rosenthal reports two instructive cases of this association. In the first labor was followed by acute cardiac insufficiency resulting from the mitral valvular lesion. The child was extracted by means of colpohysterotomy, narsosis being contraindicated. The striking feature of the case was the nonresponse of the heart to the action of roborants. She had gone through several labors successfully with the mitral lesion present. She recovered from the present labor and left the clinic with good compensation. In the second case it was not labor *per se* but labor with twins of unusual size which precipitated a crisis in the gravida with vitium cordis. This patient was also delivered by means of anterior colpohysterotomy without narcosis.

Hodgkin's Disease.—Rosenthal relates a case of this affection which he sums up as follows: A young man, previously healthy and of sound stock, was seized suddenly with chill and fever, at first thought to be of pulmonary origin. A large, firm lymphnode appeared in the neck, the spleen found enlarged, likewise the liver. A second enlarged lymphnode was found beneath the sternum. The fever assumed a recurrent type. In the intervals the spleen and liver became smaller. Leucopenia. Death took place after progressive cardiac failure, patient surviving seven months. The case was of the acute type due apparently to the liberation of some toxic agent in the blood. The only bacterium found in the lesions was the Much bacillus. As the affection remains as obscure as ever in character, the author thinks we might do worse than reconsider the old hypothesis of the tuberculous origin of the malady. Tuberculous fowls with leucemia may be made to convey the latter to other fowls. But the lymphoid swellings in Hodgkin's disease show affinities with malignant growths and no one view can be made to harmonize with all the facts.

Two Cases of Optic Neuritis after Injection of Salvarsan.—Cohen reports these cases which were evidently of the toxic type judged from the fundal finds, but

whether syphilotoxic or arsenotoxic could hardly be determined. The first case having proved refractory to antiluetic measures salvarsan was injected once. Two months later right neuritis optica appeared. The left side was affected later, but resolution followed in both eyes. A recurrence took place in the right eye, this time with permanent injury to the nerve. At the same time serous infiltration of the uvea developed, this proving readily amenable to Hg and KI which had exerted no influence on the neuritis. Arguments are adduced which make for either side of the case; these if arranged in parallel columns seem to show that the weight of evidence favors the syphilotoxic theory of the nerve lesion. Many cases must accumulate before the nature of the latter can be determined.

December 5, 1911.

Blastophthoric Degeneration.—Forel so terms the poisoning of the genital glands and germinal cells by alcohol, syphilis, opium, etc. His article is confined entirely to the effects of alcohol in this direction. That our cultured races have degenerated is shown by the increase of insanity and neuropathy, of tuberculosis, of inability of mothers to suckle, of dental caries, of percentage of army recruits rejected, etc., etc. This is due in part to the inverted selection of society which kills off its soundest men in warfare and preserves its weaklings; and in part to alcoholism. We have two resources to offset, to wit, abstinence and eugenics. Much remains to be done before the *modus operandi* of alcohol in producing blastophthoria can be completely worked out. The good ultimate results of reducing the consumption of alcohol seem to be in evidence in Sweden.

Friedländer Pneumonia.—Toenniessen as a result of clinical and experimental studies comes to the conclusion that Friedländer's bacillus can alone and of itself cause a pneumonia which pursues a characteristic course with grave prognosis. There is a notable tendency to softening, unaccompanied by any corresponding general reaction. A chill is often absent, as is also herpes. Temperatures are often low, and the prelethal rise is missed. The sputum is tenacious and rusty, at times grey. As in the case of pneumococcus pneumonia, this is due to the vast numbers of bacteria in the alveoli. However, the pneumococcus may be present in such amounts and associations that absolute causal diagnosis may be difficult. When Friedländer pneumonia does not quickly kill, passing the critical period does not greatly aid the prognosis, for fever persists, pneumonia extends, and softening occurs, until death from heart failure results, perhaps not until the fourth or sixth week. In the infrequent cases in which recovery occurs the convalescent period is prolonged, with likelihood of complications. The presence of pus often escapes recognition during life. The deadliness of Friedländer pneumonia is well shown by a material of 48 cases with but 7 recoveries.

Operative Treatment of Regular Astigmatism.—Levinsohn states that as a result of animal experiment it is now possible to operate successfully on astigmatism. He operated upon a chauffeur, whose successful employment demanded that he be able to see well without glasses, and secured a favorable result. The operation is extremely simple, consisting of a slight incision in the cornea which should always be perpendicular to the most highly refracting meridian. The author is not the first to operate, but most of our knowledge of the subject is derived from the collateral results of cataract incisions and this is not much. In animal experiment the wound is made with the galvanocautery, but the author, who operated on one of his patient's eyes in this manner, would henceforth rely wholly on the simple incision. After the latter, improvement sets in spontaneously and at once, as shown by the correction and the use of the ophthalmometer. A second incision would doubtless produce further improvement.

Adrenalinemia in Pregnancy.—Neubauer and Novak refer to the diminished carbohydrate tolerance of the gravida and the alleged increased adrenalin content of the blood serum of the latter, as shown by physiological tests. The two phenomena are believed to stand in some necessary relation to each other. It has even been thought that the progressive increase of adrenalin in the blood might be held responsible for the onset of labor. The failure to oxidize normal quantities of sugar would naturally be set down to the fact that the overproduction of adrenalin overantagonizes the action of the internal secretion of the pancreas, which is responsible for the proper carrying out of sugar metabolism. These conjectures are highly significant but, unfortunately, there is much evidence which tends to discredit them. The authors therefore proposed to revise the subject by proper experimentation, and employed as a physiological test for adrenalin the action of blood serum on the frog's blood-vessels. The rabbit's uterus method used by their predecessors was found to be much inferior to the latter. Under this method the whole superstructure previously erected appears to collapse. There is evidently no such thing as an adrenalinemia of pregnancy. Other modified tests appear to show that, as a rule, there is no essential hyperglycemia of pregnancy, although now and then a gravida may show a notably increased sugar value.

Pituitrin as an Oxytocic.—Voigt has tested pituitrin thoroughly in Prof. Bumm's clinic, Berlin, and appears to be enthusiastic over the results. Not only is the oxytocic action almost always in evidence, but by simple resort to this drug we may often dispense with metreurysis, colpeurysis, and the use of forceps. Thus far there has been little observation of unpleasant collateral or after-effects. There should be no objection to its use in private practice. The medical attendant should remain at the bedside for half an hour after the injection. The author has not yet succeeded in provoking labor by the use of pituitrin. One c.cm. was found to be a satisfactory dose in most cases. The total material comprised sixty cases, and labor pains set in in from two to ten minutes after the injection. The cases of failure were of such a type that they could be readily explained by insufficient dosage or by the fact that labor had not yet set in. In two or three cases the ordinary dose seemed to be overactive, with tendency to precipitate labor, tetanoid contractions, premature detachment of placenta, fetal asphyxia, etc., while the mother showed a tendency to collapse. These effects, however formidable, were productive of no ill consequences, but it appears that despite the severity and acuteness of the rupture of the membranes and incomplete dilatation of the os. Two children required reanimation.

Acute Pancreatitis.—Liek, in an article on the surgery of pancreatic disease reports several cases from which it appears that despite the severity and acuteness of the process a slow pulse may be present from vagus irritation. The association of slow pulse, anemia, and intestinal obstruction should suggest a possible acute hemorrhagic pancreatitis. In a second case this lesion was followed by cyst formation which being seated well toward the right side simulated dropsy of the gall bladder. The cyst, sutured to the abdominal wall and incised, gave rise to a pancreatic fistula. The latter closed for the time under Wohlgemuth's diet, but as colic and jaundice developed it recurred and was closed by operation. Pancreatic diabetes and pulmonary tuberculosis developed. Autopsy showed fibrosis of the head of the pancreas with disappearance of its body and tail.

Insurance Medicine.

SUGGESTIONS TO MEDICAL EXAMINERS.

BY THE INSURANCE EDITOR.

PERSONAL HISTORY.

UNCLASSIFIED DISEASES.—Certain disorders which are treated in regularly defined groups in the textbooks may be considered under the head of "Unclassified Diseases in Insurance Medicine" as a matter of convenience.

Malaria.—The severe forms of malaria are seldom encountered in the northern part of the United States, though a few sporadic cases appear and run a typical course in certain localities, but they practically never terminate fatally. In the South and Southwest, however, malaria of all types is so prevalent, even the dangerous forms occurring too often, that the people living there have become accustomed and indifferent to it and consequently inclined at times to ignore it when questioned by the examiner. The visitor in the South is often assured that everyone has some malaria, but that it is of no importance and does not shorten life. Nevertheless one has only to go through the hospitals in the larger cities of the South for an opportunity to study aggravated cases of malaria. Moreover, a fair proportion of death claims is presented at the home office in which malaria is given as the cause of death.

There are sections of the South and Southwest where malaria with hematuria is common, and in some spots the attacks are so pernicious and dangerous, the writer has been assured by local physicians of unquestioned authority, that the white people have had to keep out. Some years ago the writer had a large and interesting correspondence on this subject with representative physicians throughout the South and Southwest. The answers to certain interrogatories were complete and almost unanimous, to the effect that fatal cases, specially those associated with hematuria, coma, or both, still occur, but it was also explained that the diagnoses were faulty at times and that the real trouble in some instances was either incipient phthisis, gallstones, typhoid fever, intestinal autointoxication, appendicitis, or some other trouble. It was the opinion of the various writers that blood tests were seldom resorted to and that the erroneous diagnoses were entirely based on the clinical aspects of the cases.

There is no doubt that the violent and pernicious forms of malaria in the South are decidedly less frequent than in former years and that a great change has been brought about by the clearing of forests, drainage of swamps, the use of artesian wells and screening. But it must be remembered that men, while they will clear off the land and drain it for agricultural purposes, are apt to neglect their health and let up on the eternal vigilance which is required to prevent the entrance and propagation of the malaria-bearing mosquito by properly screening the houses and all vessels holding water.

The question of malaria has been dwelt on, as it is an important one not merely from its death-dealing qualities directly, but also because of its power to lower the general tone of the patients and render them less able to withstand the attacks of other diseases. As stated in the preceding lines, many individuals who have lived all their lives in malarious districts, have become as accustomed to its presence as to the air they breathe and honestly forget to acknowledge that they are or have been victims to the disease. While, then, it is undoubtedly true that deadly malaria of twenty or thirty years ago has become very much modified, it is important to get a full history of the disease, especially as to the number, dates, duration, and frequently of the attacks. The examiner should also always ascertain if there was any hematuria and, if so, whether the applicant still lives in the same locality where he originally contracted the illness; furthermore, whether the malaria was of the intermittent or remittent type, as the final decision at the home office in regard to the issuance of the policy will be largely influenced by these facts.

Infectious Fevers.—When there is a history of any acute infectious fever always ascertain the date and duration and whether there were any complications or after effects. Also state whether the applicant has fully recovered his former weight and health. In measles it is desirable to know if any pulmonary complaint followed. In scarlet fever the officials at the home office will want to know if there were any renal complications and will probably require a sample of urine sent to them for microscopical examination in recent cases.

An Endorsement of the Insurance Department.—At a meeting of the Texas Association of Medical Directors, held at Fort Worth on December 12, a resolution was unanimously passed, "endorsing the advanced stand taken by the MEDICAL RECORD in giving publication to papers and discussions dealing with the question of medical insurance work."

Reporting Diseases of Occupation.—J. B. Andrews presents a summary of recent legislation regarding the notification of the diseases of occupation. In 1911, for the first time in America, six states—California, Connecticut, Illinois, Michigan, New York and Wisconsin—enacted laws requiring physicians to report cases of occupational disease. These laws have much in common, and the diseases usually specified are anthrax, caisson disease, and lead, phosphorus, arsenic, and mercury poisoning. In Wisconsin anthrax is omitted and in Illinois the law is not quite clear in every respect, but seems to cover the usual disorders. In most cases the notification is to include the name, address, place of employment, and disease of the patient. Michigan requires, in addition, the length of time of such employment, and in New York such other information must be given as may be required by the Commissioner of Labor. In every state but Connecticut there is a penalty for failure to report, but only in California and Connecticut is compensation given for reporting. This legislation is the result of an attempt to excite interest among medical men, and for this purpose a tentative bill based on twelve years of English experience was introduced into eight state legislatures. In Minnesota action was postponed after it had been passed in one house, and in Pennsylvania it was vetoed on account of an amendment considered to be unconstitutional. The educational work, it is understood, is only begun by the enacting of these laws, and already in several states much valuable information has been obtained and boards of health and physicians are taking up the study of the subject.—*Journal of the American Medical Association*, December 16, 1911.

Accidents.—More than 35,000 deaths, it is estimated, occur every year in this country as a result of accident, and those more or less seriously injured, though not killed, number at least 2,000,000.

Book Reviews.

THE PRACTICAL MEDICINE SERIES. VOLUME VI. GENERAL MEDICINE. Edited by FRANK BILLINGS, M.S., M.D., Head of the Medical Department and Dean of the Faculty of Rush Medical College, Chicago; and J. H. SALISBURY, A.M., M.D., Professor of Medicine, Chicago Clinical School, Series 1911. Price $1.50. Chicago: The Year Book Publishers.

THIS is the second volume of the series devoted to general medicine. In it are found articles on the infectious diseases, diseases of the mouth, esophagus, stomach, intestines, liver, pancreas, and miscellaneous diseases. The book is valuable, as it covers the advances made in the diagnosis and treatment of these diseases during the past year.

THE PRACTICAL MEDICINE SERIES Volume VII. PEDIATRICS. Edited by ISAAC A. ABT, M.D., Professor of Pediatrics, Northwestern University Medical School; Attending Physician Michael Reese Hospital. With the Collaboration of MAY MICHAEL, M.D. ORTHOPEDIC SURGERY. Edited by JOHN RIDLON, A.M., M.D., Professor of Orthopedic Surgery, Rush Medical College. With the Collaboration of CHARLES A. PARKER, M.D. Series 1911. Price $1.25. Chicago: The Year Book Publishers.

THE summary of the literature of the past year covers nearly the entire field of pediatrics. An interesting case recorded is that of a transfusion performed in a newborn. The part of the book devoted to orthopedic surgery is enlivened by the critical remarks of the editors.

KURZGEFASSTE CHIRURGISCHE OPERATIONSLEHRE (OPERATIONSKURS) FÜR STUDIERENDE UND ARZTE. Von Dr. AD. OBERST, I. Assistent an der Chirurg. Klinik und Privatdozent für Chirurgie an der Universität Freiburg I. Br. With 232 illustrations, many in colors. Berlin: S. Karger, 1911.

IN this book is presented an excellent course in operative surgery on the cadaver, in which the author goes somewhat beyond the scope of most books on this subject, by calling attention in his technical instructions to the reasons why the particular operations are done in a particular manner. For this purpose he makes frequent references to the historical development of the various surgical procedures. The book is satisfactorily illustrated, although living subjects seem to serve for many of the pictures. In the section on amputations one is struck with certain of the methods employed, especially the use of the double edged transfixion knife in exarticulation of the hip, which is certainly, at the present time, not generally employed. The use of the Wyeth pins in these operations is also not referred to. This, with a number of other points, may be regarded as faults of omission, rather than of commission, and the book as a whole is very creditable.

HYMN TO HYGEIA, English and German Texts, Words, and Music. By JOHN C. HEMMETER, M.D., Ph.D., LL.D., Professor of Physiology, University of Maryland, Baltimore. Score $1.00; Parts $.50. New York: Carl Fischer, 1911.

DARWIN'S conception that the pursuit of science is necessarily associated with an atrophy of the esthetic faculties has been amply controverted by the example of many men who have achieved eminence in medical science, and who at the same time have gained recognition for their attainments in literature, music, and in the plastic and graphic arts. Holmes and Weir Mitchell are America's most shining examples of this versatility. Those of us who worship at the shrine of St. Cecilia will at once add the name of Hemmeter, whose busy professional life has not inhibited the exercise of the gift of musical composition, as exemplified in the Hymn to Hygeia.

CRIME, ITS CAUSES AND REMEDIES. By CESARE LOMBROSO, M.D., Professor of Psychiatry and Criminal Anthropology in the University of Turin. Translated by HENRY P. HORTON, M.A. With an Introduction by MAURICE PARMELEE, Ph.D., Assistant Professor of Sociology in the University of Missouri; Author of Principles of Criminal Anthropology. Boston: Little, Brown and Company, 1911.

THIS work is based upon the French version published in 1899, which was afterwards embodied by Lombroso in the third volume of the latest Italian edition of "L'Uomo Delinquente," published in 1906 and 1907. The present English translation, therefore, is the first attempt to present to English readers one of the most important of Lombroso's works, and one which was the fruit of his latest years. Although originally he had conceived the criminal as a victim of atavism, insanity, or epilepsy, presenting a distinct anthropological type, he later modified his views under the searchlight of criticism, and finally recognized the extreme importance of environmental factors in the production of criminality. The description of the economic and social causes of crime takes up the greater part of the present volume. This is divided into three parts: the first deals with the etiology of crime; the second with its prophylaxis and therapeusis; and the third with synthesis and application. In discussing the etiology of crime, the author takes up in detail and with the presentation of many statistical tables the influence of climate, race, civilization, density of population, immigration and emigration, subsistence, alcoholism, education, economic conditions, religion, profession, heredity, age, sex, civil status, prisons, and associations of criminals and the causes of political crimes. The section on the prophylaxis and therapeusis of crime deals with penology and the various substitutes for penal measures. The third part of the work discusses the relation of atavism and epilepsy in crime and in punishment, the infliction of penalties according to criminal anthropology, fines, probation systems, sex, etc.; practical applications to the criticism of criminal law, expert testimony, pedagogy, art, and science; and a chapter on the utilization of crime, *i. e.* symbiosis. This work is a veritable mine of information, arranged with the painstaking method characteristic of the scientific worker; it is replete with interest to the physician, lawyer, jurist, legislator, and sociologist. The views of Lombroso may in some instances be challenged by many readers who will not agree, for instance, with the statement that a woman convicted of infanticide should merely be put on probation with security of good behavior. Nevertheless, in the breadth of wisdom and humanity pervading his advocacy of reform in the treatment of offenders, Lombroso occupied an impregnable position and lived to see the application of his reforms in many parts of the world. Scientific penology was rendered possible only by the distinction, originally made by Lombroso, between the criminaloid, the occasional criminal, the criminal by passion, and the born criminal. In his share in the preparation of this work, the translator is to be commended for the lucidity and elegance of style with which he clothes the author's meaning. The typography, paper, and binding are in keeping with the importance of this publication.

VERÖFFENTLICHUNGEN AUS DEM GEBIETE DES MILITÄR-SANITÄTSWESEN. Herausgegeben von der Medizinal-Abteilung des Königlich Preussischen Kriegsministeriums. Heft 47. Das Königlich Hauptsanitätsdepot in Berlin. Mit 3 Tafeln und 24 Abbildungen im Text. Price 2 marks. Berlin: August Hirschwald, 1911.

THIS is a pamphlet of thirty-eight pages, describing the headquarters in Berlin of the medical division of the German army. The various forms of apparatus employed in the preparation of surgical dressings and their sterilization indicate that the German army is alive to the most modern developments in the technical phases of medical industry. This pamphlet will be found of value to army surgeons and apothecaries.

A MANUAL OF FEVERS. By CLAUDE BUCHANAN KER, M. D. (Ed.), F.R.C.P. (Ed.); Medical Superintendent, City Hospital, Edinburgh, and Lecturer on Infectious Diseases to the University of Edinburgh; Author of "Infectious Diseases: A Practical Text-Book." Price $2.50. London: Henry Frowde, Oxford University Press; Hodder and Stoughton, 1911.

THIS compact manual of 314 pages is devoted to a clinical consideration of the various exanthemata and of typhoid fever, diphtheria, erysipelas, whooping cough, mumps, and cerebrospinal meningitis. The first two chapters describe the general aspects of fever and the interpretation of rashes and of throat manifestations. Some important distinctions are made. Thus it is pointed out that fever is something more than mere pyrexia: the former is a "response in metaholism to the invasion of microorganisms and a toxic disturbance of the regulation of temperature." The statement is made that "fever can occur in persons who manifest no pyrexia, and conversely pyrexia is met with in certain nervous and hysterical conditions which do not present the other signs of true fever." As regards nomeclature the author prefers the terms "morbilli" for measles and "rubella" for German measles. The excellence of this manual consists chiefly in its careful description of the clinical signs of the common fevers, and in the emphasis placed upon the points of differentiation. Both student and practitioner will find this book a helpful guide.

Society Reports.

NEW YORK ACADEMY OF MEDICINE.

SECTION ON SURGERY.

Stated Meeting, Held December 1, 1911.

Dr. George Woolsey in the Chair.

A Case of Retrograde Incarceration in an Inguino-Femoral Hernia.—Dr. A. V. Moschcowitz presented this patient, a woman, who was admitted to Mount Sinai Hospital on November 18, with symptoms of strangulated hernia. She had had the hernia for twenty years but it had given her no trouble until eleven hours before her admission to the hospital, when she was suddenly seized with severe pain in the abdomen, followed by vomiting which soon became fecal. Prior to operation, Dr. Moschcowitz had made a diagnosis of retrograde strangulation in W-shape, in an inguino-superficial hernia. The diagnosis was partially correct. At operation only one loop of intestine was found in the sac. As the proximal loop was pulled upon for purposes of examination, there followed a blue-black, much thickened, and infiltrated loop of intestine about one and one-half yards in length. Resection was considered, but on account of the condition of the patient was decided against, and the intestine was replaced. The patient made a perfect recovery. The anatomy of the parts was most extraordinary, if not unique. The hernia was inguino-superficial, because after it escaped from the external inguinal aperture the sac turned upward and outward, and lay upon the aponeurosis of the external oblique. The hernia was of the direct variety, because the deep epigastric vessels were to its outer side. There was a complete absence of Poupart's ligament from about opposite the femoral artery to the spine of the pubis. In other words the ring through which this hernia made its escape was bounded above by the conjoined tendon, to the outer side by the deep epigastric vessels, to the inner side by the rectus, and below by the pectineus. This peculiar ring had suggested to Dr. Moschcowitz the name of "inguino-femoral hernia."

Complete Report on Bone Lesion Previously Shown.—Dr. John Gerster made this report. The patient was a boy, 10 years of age, who had been well until two months ago. His parents were intelligent and stated that he had no chronic or acute illness. After a fall his one leg became swollen and apparently longer than the other. Examination showed that the one leg was actually longer than the other. Two bony tumors were also present. The *x*-ray examination showed that there was an actual lengthening of the long bones of one and one-quarter inches and that there were two bony subperiosteal tumors of the tibia away from the epiphysis. In a child of ten, twelve, or fourteen years there were lines in the long bones parallel to the epiphyses, and as in this case in the longer side these lines were farther apart. The fibula had a uniform thickening, and there was some slight thickening of the tibia and the bones of the foot were enlarged. Both the Wassermann and the Noguchi tests were negative. Pathological examination of the bony tumors showed nothing indicative of sarcoma. They had tried 606 and this had not in any way affected the tumors, so it seemed that sarcoma and syphilis which had been suggested at the last meeting must be excluded. A search of the literature had led him to the belief that this was a case of false gigantism or hypertrophy of the bony elements. The distance apart of the lines above the epiphysis seemed to indicate that the condition was not of sudden occurrence but had been progressing for a long time. False gigantism was much more frequent than true. Congenital hypertrophy was almost never known. The bony tumors might be due to a collection of blood under the periosteum which had gradually been transformed into bony tissue. He considered the case one of false gigantism complicated by periosteal tumor.

A Cured Case of Prolapse of the Rectum.—Dr. A. V. Moschcowitz presented a young man, 23 years of age, who had had the prolapse since he was six years old. Dr. Moshcowitz said that the various operations tried to correct this condition resulted almost uniformly in failure within a few months. In thinking over these failures, he had concluded that they must consider more carefully the pathology of prolapse of the rectum, if permanent benefit was to be derived. This patient had a prolapse eight inches in length and was operated upon April 19, 1911, by the following method: Through a median laparotomy the cul-de-sac of Douglas was obliterated by several rows of purse string sutures, inserted so as to include also the deep fascia; of course care was taken not to injure the internal iliac vessels and the ureters. These were merely the fundamental principles of the operation the detailed steps of which would be published in a subsequent communication.

Dr. Howard Lilienthal said he believed that Dr. Moschcowitz was on the right track in his operations for hernia. He was much interested as he had furnished the first patient upon whom Dr. Moschcowitz had performed the operation. As to the operation for prolapse of the rectum there was no doubt but that a combined colopexy and laparotomy was the best method.

Dr. Woolsey asked Dr. Moschcowitz if he intended to state that operations for prolapse on young children were usually unsuccessful.

Dr. Moschcowitz replied that he referred only to prolapses of the rectum where all of the parts were prolapsed. With the transversalis fascia underneath the levator ani he simply formed a row of shelves which obliterated the hole that made a hernia possible. It was very difficult to repair from below; in one case he had resected the coccyx and this was not easy.

Dr. Leon T. Le Wald said that Dr. Gerster's case gave a good opportunity for calling attention to the advisability of always comparing both sides in examining a case of this kind. Many mistakes might be made by neglecting to observe this point.

The Question of Transplantation of the Cord in Operations for Hernia, with a Note on the Rôle of the Transversalis Fascia in the Production of Abdominal Hernia.—Dr. A. V. Moschcowitz read this paper. (See page 1319.)

Dr. William A. Downes said that he did not think any of them doubted the advisability of transplanting the cord. He thought the important point was to determine whether they had a direct, or a direct and an indirect hernia; in the latter case there would be weakness in the muscles of the deep epigastrium. They might leave a weak area in the transversalis fascia and most recurrences would be at that weak point. It was difficult to determine where that weak area was and if transplantation of the cord did no harm, and he could not see that it did any harm, then why not always do a transplantation?

Dr. W. C. Lusk said that in oblique inguinal hernia he had practised Halsted's technique of resecting the spermatic vessels without stripping the vas deferens together with its blood supply or the cremaster muscle out of the inguinal canal. The raising of the cord might be mutilating to the cremaster. He said furthermore that he closed the opening in the transversalis fascia at the internal ring, by including its upper edge in the sutures which united the overlying arched fibers of the internal oblique and transversalis muscles to Poupart's ligament. After the hernial sac was dissected free, a reflection of the transversalis fascia from the abdominal wall could usually be found

crossing the front of its neck, which should be cut across a little below the arched fibers, stripped it up from the peritoneal layer, and caught with a forceps for its identification when the stitches were inserted. A stitch was placed at each lateral limit of the fascial opening. Two layers of transversalis fascia might be found at this situation. Since all of the floor of the inguinal canal internal to the site of hernial protrusion in indirect herniæ was formed by transversalis fascia, which gave normally the support to the abdominal wall at this situation, it would seem that an important point in technique in reestablishing support at the internal ring would be to suture the transversalis fascia to Poupart's ligament so that it would lie closely around the cord. Dr. Lusk said he believed that recurrences were often due to an early giving way of the sutures following operation, since in most of the cases that came to a second operation the arched fibers and conjoined tendon were found back in their normal relation to the inguinal canal well above Poupart's ligament.

Dr. Howard Lilienthal said the question as to whether trauma to the cord was an evil or possibly a good thing was open to discussion. He did not mean any violence but a certain amount of surgical irritation. Slight trauma might give rise to more adhesions and thus strengthen the tissues. The lower down the opening was the greater was the care required. Whether the hernia was direct or indirect the cord should be transplanted. For a time he practised transplanting the cord and then for a time he did not do it, and he found that he had more recurrences when he did not do a transplantation. Now he transplanted in every case. He was not sure that the transplantation was responsible for the fewer number of recurrences, but it was his experience that in his cases there were fewer recurrences when the spermatic cord was transplanted.

Dr. William A. Downes said that the hernia would of course follow the line of least resistance and that would be along the spermatic cord. In doing hernia operations he had put his finger through the internal ring and had been surprised at the weakness of the transversalis fascia.

Dr. John A. Hartwell said they should remember that after operation the internal ring did not come at the original spot; they closed it and made a new spot in firmer tissue further out.

Dr. George Woolsey said that results with transplantation were as good as without. The recurrences that they saw were almost always at the inner side. If they did not transplant they could not close the opening through which the spermatic cord originally passed. As for trauma, he had seen more swollen testicles without transplantation than with it.

Dr. Moschcowitz stated that 95 per cent. of cures were claimed and conceded by everybody, but he was after the 5 per cent. of the failures. Dr. Lusk, in his remarks, had said "to close the hole in the transversalis fascia"; but they could not do this, unless they did a high castration, as room must be left for the escape of the cord into the scrotum. Dr. Downes had raised the point of weakness of the transversalis fascia to the inner side of the deep epigastric vessels; in Dr. Moschcowitz's experience, this part of the transversalis fascia was unusually strong, unless there was a direct hernia present.

Non-Suppurative Subphrenic Peritonitis Complicating Appendicitis.—Dr. Harold Neuhof presented this paper. He called attention to the fact that, while subphrenic abscess had been the subject of many communications, the possibility of the existence of a non-suppurative variety seemed to have been overlooked. A search of the literature revealed the fact that very little attention had been given to any form of subphrenic diseases other than the suppurative. The reasons that non-suppurative subphrenic peritonitis had escaped attention were that it was not fatal and therefore did not reach the autopsy room, and that exploratory punctures were far more frequently resorted to than exploratory incisions. A search of the records of the Second Surgical Service of Mount Sinai Hospital for the years 1904 to 1910, inclusive, had yielded 15 cases, which were reported in detail. Because of its greater frequency and importance, Dr. Neuhof confined himself to a consideration of this condition following appendicitis. An analysis of these cases showed that the onset of the symptoms occurred shortly after an appendiceal affection and that there was an area of localized pain and tenderness. Perihepatic friction sounds were occasionally present. The fever and blood examination together with the other symptoms indicated an intraperitoneal infection in the subphrenic region. They were apparently dealing with a variety of localized peritonitis which might be termed subphrenic peritonitis. Since subphrenic abscess might be intraperitoneally or extraperitoneally situated, it was reasonable to believe that non-suppurative subphrenic inflammations were similarly situated. He however had not seen any instance of the extraperitoneal variety of non-suppurative subphrenic inflammation, and consequently would for the time being term the condition subphrenic peritonitis. It might be argued that in the condition described as non-suppurative one or more small abscesses were formed which were not found with the aspirating needle, and that they subsided spontaneously. The history of at least one of the cases seemed to favor such a view. A parallel might be drawn between subphrenic peritonitis and pelvic peritonitis, in which condition collections of sterile pus might be found a long time after an apparently non-suppurative affection had in large part subsided. Clinically, however, both diseases ran the course of an inflammatory non-suppurative process. If a small collection of pus formed it was only secondary. In one of the cases reported such a small collection of pus was considered so incidental that the remainder of the subphrenic space, and the liver as well, were explored to find the suspected main abscess. It was most improbable that aspiration had any effect in cases in which an abscess was the central, causative factor of a subphrenic intraperitoneal exudate, unless the abscess was aspirated; yet striking effects of negative aspirations were to be seen in several instances in the cases reported. He believed, therefore, that the affection under consideration was a non-purulent one. The 15 cases occurred among 972 cases of acute appendicitis and this made its incidence about 1.5 per cent. Attempts to experimentally produce a non-suppurative subphrenic peritonitis were unsuccessful. It seemed likely that the non-suppurative condition occurred only by intraperitoneal extension. The history of two of the cases indicated that the course of the infection began in the appendiceal region, extended along the ascending colon, and terminated above the liver. The possibility of a subphrenic lymphangitis being the occasional primary lesion could not be gainsaid, and future observations might prove that the intraperitoneal subphrenic exudate was invariably due to a subperitoneal lymphangitis in that region. The physical signs in most of the cases indicated that the exudate was generally situated between the upper surface of the liver and the dome of the diaphragm. In one of the patients the inflammatory tract could be followed over the free edge of the liver to its superior surface. In another instance the entire posterior and lateral, as well as the superior, portions of the right subphrenic space appeared involved. It seemed justifiable to state that the site of election for a subphrenic exudate was that part of the space below the highest portion of the diaphragm. However, the subphrenic space appeared more widely involved in the non-suppurative than in the suppurative affection in most instances. The contents of the subphrenic exudate probably resembled

those of any other form of localized peritonitis. The right half of the diaphragm was most affected by the inflammatory process. The physical signs in this condition indicated a pronounced elevation of the diaphragm in most of the cases observed. Although no fluid was found in the pleura in any of the patients upon whom aspiration was practised, the physical signs pointed to inflammation of the pleura in several instances. An abnormally placed appendix did not seem to favor the development of the non-suppurative subphrenic affection as it did the suppurative. The symptoms of this affection were a high fever which continued to rise for several days though it could not be accounted for by retention of purulent discharge in the wound, pelvic exudate, intrapulmonary disease, etc. (in some instances the fever might be low and not of characteristic type); pain in the right lower chest, occasionally radiating to the right shoulder; possibly tenderness in one or more of the intercostal spaces near the base of the right axilla, perihepatic friction sounds, and some dullness to percussion at the base of the right axillary zone. The patient might cough, usually without expectoration. The fever pursued a high and irregular course in typical cases. The pulse was slow in proportion to the temperature, and respirations were normal in rate. The patients were usually not profoundly prostrated. The blood examination almost invariably indicated an acute inflammatory process. Intercostal tenderness and rigidity were most pronounced in the 7th, 8th, and 9th spaces. The liver percussion was normal, but the edge of the liver might be felt a short distance below the costal margin. There was dullness to percussion over the lower part of the right chest. The area of dullness was greatest in the axilla and might reach as high as the level of the angle of the scapula; under such circumstances a pleural effusion was probably present, although fluid might not be found in the pleura at any of the exploratory aspirations. Vocal fremitus, voice, and the respiratory murmur were diminished over the dull area; the voice sounds were often faintly tubular in character. The physical examination did not always reveal these typical findings.

The course of non-suppurative subphrenic peritonitis appeared to be very variable, lasting from five to thirty days. As to the after effects of the affection, only seven patients could be traced after leaving the hospital; all of these remained free from symptoms except one. In this instance some permanent change had apparently occurred in the subphrenic space. The differential diagnosis between suppurative and non-suppurative subphrenic inflammation was not always an easy matter, but in general an appendix abnormally situated favored subphrenic abscess and in the suppurative affection the symptoms did not usually appear until weeks, even months, after the appendiceal attack or operation. The symptoms in patients who were the subjects of subphrenic abscess were decidedly more serious in most instances. In typical instances of subphrenic abscess the liver was considerably displaced, intercostal tenderness was often localized in two or three points, not widespread as in the non-suppurative process; there might be bulging of the lower part of the thorax on the right side, the physical signs in the chest were more pronounced, and considerable fluid might be found in the pleural cavity. Aspiration had no effect on the subphrenic abscess, while it appeared to decidedly influence the non-suppurative variety. There should be little difficulty in differentiating liver abscess, complicating appendicitis, from non-suppurative subphrenic peritonitis. In the suppurative and non-suppurative subphrenic inflammations pain was elicited upon intercostal pressure, especially in the 7th, 8th, and 9th spaces in the axillary zone, but not upon pressure over the lower right thoracic wall with the flat of the hand. The latter procedure, on the contrary, elicited pain in patients having a liver abscess, acute hepatitis, congestion of the liver, whereas intercostal pressure might be quite painless in these hepatic affections. Although aspiration was only employed for diagnostic purposes, it appeared to have been followed by a distinct therapeutic result in seven of the nine cases in which it was employed. In these instances the procedure was followed by an almost critical drop in temperature and a recession in the symptoms. It was impossible to offer an adequate explanation of this phenomenon. Whatever the explanation might be, however, Dr. Neuhof said, aspiration certainly seemed to have a salutary effect on the course of the disease.

Dr. Robert T. Morris said that the question as to the route by which infection traveled was not as important as that of resistance. They were well aware of how an active colony of colon bacilli were taken up by the afferent vessels and carried along. When the bacilli traveled over a free surface the places where they were intercepted and met resistance on the part of the protective cells were shown by adhesions. While bacilli might not cause a terminal suppurative process, they might travel quite freely over the free surface of the peritoneum and find that same lack of protection which was often found to exist in relation to the colon bacilli traveling on the free surface of the pylorus.

Dr. Howard Lilienthal said that it seemed odd that the possibility of non-suppurative peritonitis in this region had not occurred to them before. The paper reminded him of two cases in his experience. In one there was certainly a non-suppurative collection of fluid in the subphrenic region. After an operation the patient had high fever and it looked as though there was suppuration somewhere. They aspirated the subphrenic region and got about two drams of a clear straw-colored fluid. True to the type referred to in the paper, the patient immediately got well. In the short time of twenty-four hours the improvement was so great that there was no longer any cause for alarm. His opinion of the case at the time was that the fluid would have become purulent if there had been no interference. The second case was that of a pregnant woman, who had been operated upon for appendicitis, aborted, and then developed a pneumonia. After the pneumonia, the solidification in the chest did not disappear. The liver was swollen but was not pushed downward. They aspirated many times with negative findings and the patient did not improve. Finally they opened the chest and found a superphrenic abscess containing four or five ounces of pus. In this case he thought there was a non-suppurative process at first which later caused the thoracic abscess. He recalled several other cases that got well after being aspirated.

Dr. Neuhof, in closing the discussion, said that the way in which the subphrenic space became involved in an infective process recalled to his mind an experiment by which lampblack was introduced in the femoral region and it was found that it traveled up on the surface of the peritoneum; the leucocytes high up in the abdomen contained more or less lamp black.

Acute Hemorrhagic Pancreatitis.—Dr. Charles E. Farr presented this specimen, which had been removed from a woman, 45 years of age, who had gall-bladder trouble for two years, but who persistently refused operation. Finally, when her condition became desperate, she agreed to the operation and thirty-five gallstones were removed from the gall-bladder and common duct. The patient did not survive; at autopsy they found forty-six gallstones. The pancreas showed an acute hemorrhagic inflammation. The duct of the pancreas opened into the duodenum but had no opening into the common duct of the gall-bladder.

Election of Officers.—*Chairman*, Dr. Lucius Wales Hotchkiss; *Secretary*, Dr. Arthur Seymour Vosburgh.

State Medical Licensing Boards.

STATE BOARD EXAMINATION QUESTIONS.

STATE OF MISSISSIPPI.

October 10-11, 1911.

ANATOMY.

1. Explain bone development and give examples.
2. Describe hip joint, naming its ligaments.
3. Give origin, course, and distribution of third cranial nerve.
4. Name the preaxial muscles, giving the insertion of any one of them.
5. What constitutes the lymphatic system, and how connected?
6. Locate the emissary veins and give clinical importance.
7. Name abdominal viscera wholly covered by peritoneum.
8. Give nerve and blood supply of the rectum.

PHYSIOLOGY.

1. Describe the sounds of the heart and give causes.
2. Describe and give function of the Haversian canal.
3. Discuss (*a*) emulsification and (*b*) saponification.
4. Discuss fully rigor mortis.
5. Discuss minutely the excretion of urine.
6. Give the secretions of the alimentary canal, give the reaction and active principles of each one.
7. Discuss, fully, respiration.
8. Give function of adipose tissues.

CHEMISTRY.

1. Give the chemical formulæ of the following substances: (*a*) Iron sulphate, (*b*) hydrocyanic acid, (*c*) corrosive sublimate, (*d*) zinc sulphate.
2. What test would you use or employ to determine the presence of organic matter in drinking water?
3. In what combination is phosphorus found in nature?
4. Give antidote for corrosive sublimate, and explain its action.
5. Give the name and general physical and chemical properties of the halogens.
6. What physical actions have a tendency to decompose compound substances?
7. Name four chief elements entering into the formation of organic compounds.
8. In testing urine for sugar explain the reaction where Haines' solution is used.

MATERIA MEDICA.

1. Give source and uses in medicine of ichthyol.
2. Give the official name, composition, and usual dose of Fowler's solution and Donovan's solution.
3. Name the two alkaloids of opium usually used, and give doses. Also name and give doses of two derivatives of morphine.
4. What active principles are found in digitalis? Name the official preparations and doses; and say in what conditions digitalis is contraindicated.
5. Give hypodermic doses of the following: Strychnine sulphate, atropine sulphate, nitroglycerin, physostigmine; and compare the therapeutic uses of atropine with nitroglycerin.
6. Give the common name, therapeutic uses, and dose of sodium sulphate.
7. Name the principal alkaloid and official preparations of aconite, and state their doses, and give physiological action, and name conditions that contraindicate the use of aconite. Name antidotes.
8. Give source, dose, and indications for salol, and name the drugs it is subdivided into after administration.

PATHOLOGY.

1. What conditions might cause cyanosis of the face, jugular pulsation, and general anasarca?
2. What is the pathology of suppurative inflammation, and of plastic inflammation?
3. What is the pathology of a decayed tooth (physiological)?
4. What is the gross pathology of arthritis deformans?
5. Give pathological characteristics of medullary type of carcinoma of the breast.
6. Enumerate the pathological sequences of diphtheria.
7. Give gross pathology of endocarditis and mention most frequent causes.
8. Describe step by step the process involved in simple inflammation.

SURGERY.

1. Name all the agents employed for the production of general and local anesthesia, and give treatment for overdose of each.
2. Name in order of their virulence the bacteria of suppuration.
3. Name all the conditions requiring trephining, and describe the operation.
4. Give symptoms and treatment of psoas abscess.
5. Describe an osteoclast, and give indications for its use.
6. Give a clear description of a perineal prostatectomy.
7. Give cause and treatment of esophageal stricture.
8. Describe paracentesis tympani, and give indications for the procedure.

OBSTETRICS.

1. Describe methods to determine position of the fetus previous to labor.
2. State the danger to the cord in the various stages of labor and describe the methods of overcoming these dangers.
3. For what conditions and at what periods of time should cesarean section be performed?
4. Name four causes of dystocia with treatment of any one form.
5. Describe delivery in a case of breech presentation requiring the application of forceps.
6. Define involution and subinvolution.
7. What are after-pains? State their cause and give treatment.
8. Name the fetal evelopes from without inward.

HYGIENE.

1. What are the reasons for abolishing the common drinking cup?
2. Name and describe three intestinal parasites, and how would you prevent infection by each?
3. What hygienic instructions should be given to patients with tuberculosis?
4. What are the principal adulterations of milk?
5. Describe in detail the methods of transmission of yellow fever and malarial fever.
6. Give period of incubation, time for quarantining and mode of disinfecting after five diseases.
7. When should persons who have been infected with gonorrhea or syphilis be permitted to marry?
8. Differentiate between endemic and epidemic diseases.

ANSWERS TO STATE BOARD EXAMINATION QUESTIONS.

STATE OF MISSISSIPPI.

October 10-11, 1911.

ANATOMY.

1. See Cunningham's "Anatomy" (1909), pages 73 and 74; or Gray's "Anatomy" (1910), pages 42 and 44.
2. See Cunningham's "Anatomy" (1909), page 293; or Gray's "Anatomy" (1910), page 322.
3. See Cunningham's "Anatomy" (1909), page 676; or Gray's "Anatomy" (1910), page 979.
4. *The preaxial muscles* are: Pectoralis major, pectoralis minor, subclavius, coracobrachialis, biceps, brachialis anticus, pronator radii teres, flexor carpi radialis, palmaris longus, flexor carpi ulnaris, flexor sublimis digitorum, flexor profundus digitorum, flexor longus pollicis, pronator quadratus, palmaris brevis, abductor pollicis, opponens pollicis, flexor brevis pollicis, abductor minimi digiti, opponens minimi digiti, flexor brevis minimi digiti, adductor pollicis, interosseous, psoas magnus, iliacus, pectineus, gracilis, adductor longus, adductor brevis, adductor magnus, quadratus femoris, obturator externus, obturator internus, gemellus superior, gemellus inferior, biceps femoris, semitendinosus, semimembranosus, gastrocnemius, soleus, plantaris, flexor longus digitorum, flexor longus hallucis, tibialis, posticus, flexor accessorius, popliteus, flexor brevis digitorum, flexor brevis hallucis, abductor hallucis, abductor minimi digiti, lumbricales, adductor hallucis, interosseous, flexor brevis minimi digiti.

The pectoralis minor is inserted into the coracoid process of the scapula.

5. See Cunningham's "Anatomy" (1909), page 904; or Gray's "Anatomy" (1910), page 770.
6. *Emissary veins:* "These are communications between the sinuses within and the veins outside the cranium. Most of them are temporary, corresponding to the chief period of growth of the brain. Thus in early life, when the development of the brain has to be very rapid, owing to the approaching closure of its case, a free escape of

blood is most essential, especially in children, with their sudden explosions of laughter and passionate crying. (1) Vein through the foramen cæcum, between the anterior extremity of the superior longitudinal sinus and the nasal mucous membrane. The value of this temporary outlet is well seen in the timely profuse epistaxis of children. Other more permanent communications between the skull cavity and nasal mucous membrane pass through the ethmoid and internal orbital foramina. The fact that the nasal mucous membrane is loose and ill supported on the turbinated bones allows its vessels to give way readily, and thus forms a salutary safeguard to the brain, warding off many an attack of apoplexy. (2) Vein through the mastoid foramen, between the lateral sinus and the posterior auricular and occipital veins. This is the largest, the most constant, and the most superficial of the emissary veins. Hence the old rule of applying blisters or leeches over it in cerebral congestion. (3) Vein through the posterior-superior angle of the parietal between the superior longitudinal sinus and the veins of the scalp. (4) Vein through the posterior condyloid foramen between the lateral sinus and the deep veins of the neck. (5) Vein through the anterior condyloid foramen between the occipital sinus and the deep veins of the neck. (6) Ophthalmic veins communicating with the cavernous sinus and the angular vein. These veins may be the source of fatal blood-poisoning, by conveying out of reach septic material, in acute periostitis of the orbit, or in osteitis, of dental origin, of the jaws. (7) Minute veins through the foramen ovale between the cavernous sinus and the pharyngeal and pterygoid veins. (8) Communications between the frontal diploic and supraorbital veins, between the anterior temporal diploic and deep temporal veins, and between the posterior temporal and occipital diploic veins and the lateral sinus. The gravity of these emissary veins and their free communications with others is shown by the readiness with which they become the seat of septic thrombosis, and thus of blood-poisoning, in cranial injuries, erysipelas, suppuration of the scalp, and necrosis of the skull." (Morris' *Anatomy.*)

7. *Abdominal viscera wholly covered by peritoneum:* Stomach, first part of duodenum, jejunum, ileum, cecum, transverse colon, sigmoid flexure, first part of rectum, liver.

8. RECTUM. *Nerve supply:* Sympathetic plexuses (inferior mesenteric and hypogastric), fibers from the second third, and fourth sacral nerves. *Blood supply:* Superior, middle, and inferior hemorrhoidal arteries and veins.

PHYSIOLOGY.

1. There are two normal heart sounds which follow in quick succession, and are succeeded by a pause. The first, or systolic, sound is dull and somewhat prolonged, the second, or diastolic, sound is sharper and shorter. The sounds may be expressed by the syllables *lubb—dup.*

The first sound is heard best at the apex beat in the fifth left intercostal space; the second sound is heard best over the second right costal cartilage.

The *causes* producing the *first* sound of the heart are not definitely ascertained; the following are supposed to be causatory factors: (1) The vibration and closure of the auriculo-ventricular valves, (2) the muscular sound produced by the contraction of the ventricles, and (3) the cardiac impulse against the chest wall.

The *second* sound is caused by the vibration due to the closure of the semilunar valves.

2. See Cunningham's "Anatomy" (1909), page 72; or Gray's "Anatomy" (1910), page 39. *The function of the Haversian canals:* They serve to conduct arteries, veins, lymphatics, and nerves to and from the bone substance.

3. *Emulsification* is a physical process by which fat globules are split up into very minute particles capable of being absorbed by the villi of the intestine.

Saponification is a chemical process by which a fatty acid in combination with an alkali produces a soap and glycerin.

Both of these processes are accomplished by the steapsin of the pancreatic juice.

4. *Rigor mortis* is a condition of rigidity assumed by the muscles after death. It is supposed to be due to the coagulation of the myosinogen. The muscles lose their irritability and pass into a condition of contraction. Heat is evolved, carbon dioxide is given off, and the muscles become acid in reaction due to the development of sarcolactic acid. Rigor mortis usually sets in first in the muscles of the lower jaw, face, and neck, then in those of the thorax, abdomen, upper extremity and lower extremity. It usually lasts for from twenty-four to forty-eight hours, and disappears in the same order as the onset.

5. *Excretion of urine:* According to Bowman's theory, the watery part of the urine (with the soluble inorganic salts) is filtered from the capillaries in the glomerulus through the flattened epithelial cells of Bowman's capsule, into the lumen of the uriniferous tubule; and the nitrogenous substances (urea, uric acid, creatinin, etc.) are excreted by the cubical cells lining the tubules.

6. SECRETIONS OF ALIMENTARY CANAL. (1) *Saliva,* alkaline; active principle, ptyalin. (2) *Gastric juice,* acid; active principles, pepsin and rennin. (3) *Pancreatic juice,* alkaline; active principles, trypsin, amylopsin, steapsin, and a milk-curdling ferment. (4) *Succus entericus,* alkaline; active principle, invertin. (5) *Bile,* alkaline; it contains no "active principles," but bile salts (sodium taurocholate and sodium glycocholate), and bile pigments (bilirubin and biliverdin).

7. *Respi ation* is the process by which an interchange of gases takes place in the lungs; so that oxygen is introduced and carried to the tissues, and carbon dioxide is expelled. See Gray's "Anatomy" (1910), page 423.

The changes produced in the *air* by respiration are:

	INSPIRED AIR.	EXPIRED AIR.
Oxygen	21 per cent.	16.6 per cent.
Nitrogen	79 per cent.	79 per cent.
Carbon dioxide...	0.04 per cent.	4.4 per cent.
Other gases.....	Rare.	Often present.
Watery vapor....	Variable.	Saturated.
Temperature	Variable.	That of the body.
Volume	Varies.	Diminished.
Bacteria	Always present.	None.
Dust	Always present.	None.

8. *Function of adipose tissue:* (1) It is a reserve store of food; (2) it serves as a protection for delicate structures; (3) it preserves the heat of the body.

CHEMISTRY.

1. Chemical formula, of iron sulphate, $FeSO_4$; of hydrocyanic acid, HCN; of corrosive sublimate, $HgCl_2$; of zinc sulphate, $ZnSO_4$.

2. As a rule a solution of potassium permanganate will be rapidly decolorized in the presence of organic matters. If such organic matter is nitrogenous it can be detected by the Wanklyn or Frankland method.

3. Phosphorus is found in nature as phosphate (chiefly calcium phosphate).

4. Antidote for corrosive sublimate is milk or white of egg; this forms the albuminate of mercury, which is insoluble.

5. The *halogens* are: Fluorine, chlorine, bromine, and iodine. They are all univalent; they form hydracids; they are all irritant and corrosive; they all possess bleaching and disinfecting properties; their hydroxides (except fluorin, which has none) are monobasic acids.

6. *Physical actions which have a tendency to decompose compound substances:* Light, heat, and electricity.

7. *Four chief elements entering into the formation of organic compounds:* Carbon, hydrogen, oxygen, and nitrogen.

8. In testing urine for sugar, with Haines' solution: By the action of the boiling alkaline solution glucose is converted into substances which (being prone to oxidation) are good reducing agents. These latter reduce the cupric sulphate into cuprous sulphate, and this in time is decomposed with the deposition of cuprous oxide.

MATERIA MEDICA.

1. Ichthyol is obtained from ichthyosulphuric acid, which comes from a crude oil obtained by destructive distillation of fossil fish found in the earth in the mountains of Tyrol. It is used in inflammatory conditions generally, erysipelas, ulcers, indurated glands, joint affections, rheumatism, certain chronic skin diseases, chronic inflammations of the pelvic viscera, and in gynecological practice.

2. FOWLER'S SOLUTION. *Official name:* Liquor potassii arsenitis. *Composition:* Arsenic trioxide 10, potassium bicarbonate 20, compound tincture of lavender 30, and distilled water to 1,000. *Dose:* Three minims.

DONOVAN'S SOLUTION. *Official name:* Liquor arseni et hydrargyri iodidi. *Composition:* Arsenous iodide 10, red mercuric iodide 10, distilled water to 1,000. *Dose:* One and a half minims.

3. *Two alkaloids of opium:* Morphine, *dose* gr. ¼; and codeine, *dose* gr. ½.

Two derivatives of morphine: Apomorphine, dose of the hydrochloride (as an emetic) gr. 1/10; and dionin, *dose* gr. ¼.

4. DIGITALIS. *Active principles:* Digitalin, digitalein, digitin, digitonin, and digitoxin. *Official preparations and doses:* Fluidextract, ♏j; extract, gr. 1/5; tincture, ♏xv; infusion, 5ij. *Digitalis is contraindicated* in: Diseases of the heart, (1) in aortic lesions, when uncombined with mitral lesions; (2) when the heart action is strong and arterial tension high.

5. *Hypodermic dose* of: Strychnine sulphate, gr. 1/60; atropine sulphate, gr. 1/180; nitroglycerin, ½ minim of a 1 per cent. solution; physostigmine, gr. 1/100.

Therapeutic uses of atropine: To relieve pain, relax spasm, check sweating, as a mydriatic, for night sweats, to check griping of purgatives; in asthma, to check fevers, in heart disease, shock, and collapse, acute coryza, urinary incontinence, chordee, low delirium of fevers, mania, alcoholism; as an antigalactagogue, and for spasmodic cough.

Therapeutic uses of nitroglycerin: In renal degeneration with high arterial tension, angina pectoris, cardiac dyspnea, epilepsy, various spasmodic conditions.

6. SODIUM SULPHATE. *Common name:* Glauber's salt. *Therapeutic uses:* As a saline purgative, as a cholagogue, for gallstones, also in nervous diseases. *Dose:* 5iv.

7. ACONITE.. *Principal alkaloid.* Aconitine, dose gr. 1/400. *Official preparations:* Fluidextract, dose ♏j; tincture, ♏x.

Physiological action: It first stimulates, and then paralyzes the heart and also the sensory nerves, lowers blood pressure, dilates the peripheral blood-vessels, is a respiratory sedative, reduces body temperature, is a diuretic and diaphoretic. It is *contraindicated:* In adynamia, weak cardiac action, degeneration or dilatation of the heart, and gastrointestinal irritation or inflammation. *Antidotes:* Digitalis, atropine, and strychnine.

8. SALOL. *Source:* Heating phenol and salicylic acid in the presence of phosphorus pentachloride. *Dose:* Gr. vij. *Indications:* As a disinfectant, in inflammations of the mouth and pharynx, in cystitis, as an intestinal antiseptic in typhoid fever, in muscular rheumatism, in intestinal indigestion and fermentation, and in colera. *After administration it is subdivided into:* Salicylic acid and phenol.

PATHOLOGY.

1. *Cyanosis of the face* might be caused by: Valvular disease of the heart, myocarditis, emphysema, asthma, pneumonia, phthisis, bronchitis, foreign body in the air passages.

Jugular pulsation might be caused by: Tricuspid regurgitation, anemia, thoracic aneurysm communicating with the superior vena cava.

General anasarca might be caused by: Cardiac disease, or weakness, renal disease, multiple neuritis, trichinosis, Hodgkin's disease.

2. See French's "Practice of Medicine" (1910), pages 42 and 43; or Da Costa's "Surgery" (1908), pages 77, 81, and 82.

3. *Pathology of a decayed tooth:* "The primary stage of caries is determined by the presence at a certain portion of a tooth of an acid capable of dissolving the inorganic salts. The matrix of the prisms is the first to be dissolved, and into the spaces thus formed crowd organisms which, given a suitable pabulum, produce more acid and further destruction of the surrounding tissue. There is good reason to believe that, apart from its natural resistance to solution, the enamel offers no vital resistance to attack. After the solution of the enamel the dentine is decalcified in a similar manner, and later the remaining organic portion of the tooth substance is digested by the bacteria, which perform their work by means of secreted enzymes, digesting the tissue in much the same way as the pepsin of the gastric juice acts upon albuminous materials. . . . Dental caries is, as a rule, a progressive disease, but under certain conditions its progress becomes arrested. In such cases the teeth generally show an extensive loss of tissue, the enamel of the masticating surfaces, and even of the sides, having disappeared. The exposed dentine is darkly stained, and presents to the eye a polished appearance. An examination with a probe will show that the dentine is as hard as, if not harder than, in the normal condition. This state, which is known as *spontaneous arrest of caries,* may be found in both the deciduous and permanent teeth; in the latter the condition is most frequently met with in hypoplastic first permanent molars. It occurs only in teeth with living pulps, and the appearance of the teeth suggests that the disease, when active, was of a general and rapid character. Miscroscopical examination shows that the dentine retains the color of carious dentine, or is perhaps slightly darker. The dentinal tubes, which can be easily seen in the discolored part, end apparently upon the surface."—(Colyer's *Dental Disease*).

7. See French's "Practice of Medicine" (1910), pages 578 and 577; or Osler's "Practice of Medicine" (1909), pages 786 and 785.

8. See Rose and Carless' "Surgery" (1908), page 31; or Da Costa's "Surgery" (1908), page 73.

SURGERY.

1. *General anesthesia* may be produced by: Ether, chloroform, nitrous oxide, ethyl chloride; *local anesthesia,* by: Cocaine, eucaine, ethyl chloride. There are others, but these are the most commonly used. For overdose of any of the general anesthetics, remove the inhaler, and start artificial respiration, make traction on the tongue, lower the patient's head, or invert him, give hypodermic of atropine, apply faradism to the phrenic nerve, put hot water bottles to the extremities, let plenty of fresh air into the room, give an enema of hot salt solution; in some cases of chloroform poisoning direct heart massage has been employed. The sphincter ani may be stretched; and bleeding from the external jugular vein may be tried.

2. *Bacteria of suppuration: Staphylococcus pyogenes aureus, Staphylococcus pyogenes albus, Staphylococcus pyogenes citreus, Streptococcocus pyogenes. Bacillus pyocyoneus, Micrococcus tetragenas,* gonococcus, colon bacillus, typhoid bacillus, pneumococcus. The *order of virulence* is not settled.

3. *Indications for trephining:* "Intracranial hemorrhage, abscess, fracture, foreign body, evacuation of cerebrospinal fluid through the lateral ventricle, as a preliminary step to osteoplastic resection and to linear craniectomy, epilepsy, bullet and other wounds, small tumors, drainage of frontal sinus, drainage of mastoid antrum and cells, thrombosis of venous sinuses."—(Bickham's *Operative Surgery.*) See Rose and Carless' "Surgery" (1908), page 758; or Da Costa's "Surgery" (1908), page 734.

4. See Rose and Carless' "Surgery" (1908), pages 723 and 730; or Da Costa's "Surgery" (1908), pages 134, 151, and 156.

5. An *osteoclast* "is an instrument consisting of a bar on which are two padded rings, and between them a padded metal plate, connected with a screw; the pressure exerted by this screw breaks the bones of the limb placed through the rings."—(Scott's *State Board Surgery.*) *Indications for its use:* Knock-knee, bow-legs, and fractures which have united with great deformity.

6. See Rose and Carless' "Surgery" (1908), page 1230; or Da Costa's "Surgery" (1908), page 1191.

7. *Causes of esophageal stricture:* (1) *Intraesophageal* —foreign body, mass of food. (2) *Interstitial*—Neoplasm; cicatricial tissue, as from toxic gastritis, ulcer (syphilitic, peptic); esophageal abscess; diverticula filled; congenital; spastic structure. (3) *Extraesophageal*—Enlarged glands (sternal, cervical, bronchial, from tuberculosis, cancer, suppurative adenitis); mediastinal or cervical cellulitis; vertebral disease; dislocation of hyoid bone or clavicle; cancer of pleura or lung; ossification of stylohyoid; ligament, swelling of cricoid; pericardial effusion, cardiac hypertrophy, aneurysm. For *treatment,* see Rose and Carless' "Surgery" (1908), page 877; or Da Costa's "Surgery" (1908), page 803.

8. See Rose and Carless' "Surgery" (1908), page 882. *The indications for paracentesis tympani* are: Undue distention in otitis media, hyperemia, and infiltration of the membrana tympani, or for purposes of exploration.

OBSTETRICS.

1. See Williams' "Obstetrics" (1909), pages 207 and 211; or Hirst's "Obstetrics" (1909), page 389.

2. See Index of Williams' or Hirst's "Obstetrics," under heading "Umbilical Cord."

3. See Williams' "Obstetrics" (1909), page 443; or Hirst's "Obstetrics" (1909), page 857.

4. *Four causes of dystocia:* Uterine inertia, deformed pelvis, transverse presentation, and uterine displacement. For *uterine inertia,* see Williams' "Obstetrics" (1909), page 661; or Hirst's "Obstetrics" (1909), page 442.

5. See Williams' "Obstetrics" (1909), pages 419 and 429; or Hirst's "Obstetrics" (1909), pages 824 and 826.

6. *Involution* is the process by which the uterus, after labor, returns as far as possible to its original size. *Subinvolution* is any arrest or retardation of the process of involution.

7. See Williams' "Obstetrics" (1909), pages 337 and 341; or Hirst's "Obstetrics" (1909), page 356.

8. Decidua, chorion, and amnion.

HYGIENE.

1. By the use of a common drinking cup disease may be transmitted; it is also an unsanitary and unclean habit.

2. See French's "Practice of Medicine" (1909), pages 481 and 485; or Osler's "Practice of Medicine" (1909), page 28.

3. Hygienic precautions to be taken in treating a case of tuberculosis: "The patient's quarters should be free from dust and admit of spending many hours daily in the open air in all weathers, properly sheltered, and, if very ill, lying wrapped in a hammock or reclining chair. His bedroom should be well aired at night, drafts being avoided. The room should be uncarpeted and free from hangings. It should be often cleaned and periodically disinfected. All sputum should be collected in paper spit-cups, which should be burned daily. Smoking should be forbidden. Harm is done by any exercise which results in fatigue, and while fever exists it should not be attempted at all. Patients should be taught the necessity of practising lung gymnastics and breathing only through the nose, which should be kept clear and free from occlusion by secretions, or an hypertrophied catarrhal mucosa. * * * The clothing should be woolen, but not too heavy, or sweating is increased; and a flannel nightgown and loosely knit leggings should be worn at night in cool weather. The skin should be cleansed by daily sponge-baths of lukewarm alcohol and water."—(Thompson's *Practical Medicine.*)

4. *Milk may be sophisticated or adulterated* by: (1) Skimming; (2) the addition of water; (3) the addition of coloring matter, such as caramel, annatto, or methyl orange; (4) the addition of preservatives, as boric acid, formaldehyde, salicylic acid, or salicylates; (5) the addition of arrowroot, flour, sugar, glycerine, chalk, or sodium carbonate.

5. Malaria is *caused* by the *Plasmodium malariæ*, but *carried* by the anopheles mosquito. The cause of yellow fever is not yet determined, but it is *carried* by the stegomyia mosquito. And see French's "Practice of Medicine" (1910), pages 233 and 267; or Osler's "Practice of Medicine" (1909), pages 10 and 233.

6. See French's or Osler's "Practice of Medicine." For *disinfection of rooms*, use formaldehyde gas; *clothing*, use solution of phenol (5 per cent.) for an hour, then boil for an hour; *person*, wash in soap and water, and then with cresol or carbolic acid solution; *bedding*, use steam or formalin; *excreta*, etc., should be passed into vessels containing dilute solution of formalin, of greater quantity than the expected excretion.

7. "The physician consulted by a patient with *gonorrhea* who wishes a professional sanction to his marriage should demand a period on an average of six months.

"The general rule which may be formulated as safe for a *syphilitic* man to marry, so far as contagious risks to his wife are concerned, is that a period of four years should have elapsed since the chancre; that he should have been free from manifestations during the last twelve or eighteen months of this period, and that he should have received sufficient specific treatment."—(Morrow's *Social Diseases and Marriage.*)

8. An *endemic* disease is one that is always more or less prevalent in a certain locality. An *epidemic* disease is one that attacks simultaneously, or in rapid succession, many persons in the same locality; or that spreads rapidly over a large territory.

Puerperal Psychoses.—Lucien Picque distinguishes among psychoses connected with pregnancy and the puerperal state between febrile states accompanied by delirium, which he considers to be always due to an infection of the uterus of more or less degree of severity, and the afebrile ones. The febrile cases should always indicate an evacuation of the uterus and should be treated only in a hospital where surgery is done and not in an asylum. The apyretic cases may be sent to an asylum. The uterine wound should serve as a line of separation between the psychoses of pregnancy and of the puerperal state. While there must always be a predisposition to mental trouble, still it is the results of infection that make the condition incurable. If the uterus is early excuated one may get a cure, but if the condition of infection become chronic there shall get changes in the brain cells that will render the condition permanent. In the apyretic forms we generally observe meloncholia; in the febrile form confusion, hallucinations and maniacal attacks. The apyretic forms should go to an asylum, the febrile to a surgical hospital.—*L'Obstétrique*, July, 1911.

Medical Items.

Contagious Diseases, Weekly Statement.—Report of cases and deaths from contagious diseases reported to the Sanitary Bureau, Health Department, New York City, for the week ended December 23, 1911:

	Cases	Deaths
Tuberculosis Pulmonalis	436	171
Diphtheria	282	23
Measles	483	5
Scarlet Fever	180	8
Smallpox	—	—
Varicella	257	—
Typhoid Fever	70	14
Whooping Cough	20	—
Cerebrospinal Meningitis	4	3
Malarial Fever	—	—
Totals	1,732	224

Hemorrhagic Manifestations in Mental Disease.—G. Boschi describes an epidemic of hemorrhagic disease which appeared in the Provincial Insane Asylum of Sondrio. The manifestations were similar to those of peliosis, Werlhoff's disease, and scurvy and were associated in various ways. The author thinks that we are not justified in distinguishing types of disease and denominates them all hemorrhagic disease. The epidemic appeared in the spring, which was very damp and very late that year. About 25 per cent of the men and 10 per cent of the women were sick, but none of the attendants. This shows the great importance of predisposition in this kind of hemorrhagic disease, which the author thinks consists in a series of conditions having some relation to the presence of the insane. These patients had some cortical alterations due to their mental alienation. There was a vulnerability of the nervous system consequent upon or accompanying the mental disturbances, making the patient an easy prey to hemorrhagic disease. The author advances the hypothesis of a difficulty of adaptation of the vasomotor centers due to climate and altitude.—*La Riforma Medica.*

Health Reports.—The following cases of and deaths from smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General, Public Health and Marine Hospital Service, during the week ended December 22, 1911:

Places	Date	Cases	Deaths
CHOLERA			
India: Calcutta	Oct. 22–Nov. 4		152
Madras	Nov. 5–18	167	126
Madras presidency, Oct. 1–31	Cases 3,043, deaths 1,675.

INDEX.

A.

Abdomen, abnormalities of, 1190; drainage from, 1152; free gas in cavity of, as differentiated from tympanites, 820; incisions of, 687; injuries of, 1044; obese wall of, 1002; surgical treatment of ptosis of organs of, 104; surgery of, 340; surgery of, employment of two rubber drainage tubes in, 105; symptoms of, in thoracic disease, 26; upper, significance of pain in, 1152; viscera of, in autointoxication and autoinfection, 950; viscera of, traumatic rupture of, 736; wall of, inflammatory tumors of, 888; wall of, surgery of, 1338.

Abortion, missed, 430.

Abscess, occipital, 440; perirectal, 376; subphrenic, following appendicitis, 440.

Abstinence, sexual, 783, 1042.

Academy of Medicine in Paris, 140.

Acanthosis nigricans, 705.

Acetanilid, chronic poisoning by, 140, 439.

Acetone, diagnostic value of, in gynecological surgery, 430.

Acetonuria, in diphtheria and acute angina, 937; in childhood, 1091; in pregnancy, 788.

Achroodextrin in stomach contents, 834.

Acidosis, diabetic, rectal infusion of sugar solutions in, 587.

Acromegaly, 906; and dystrophia adiposo-genitalis, 489; urine in, 86.

Actinomycosis, see streptothricosis.

Adams, E., differential diagnosis of lymphomata of the neck, 523.

Addison's disease, sugar metabolism in, 538.

Adenoids, and tonsils as related to retarded physical and mental development, 475; and tonsils, surgical treatment of, 907; in school children, 378; operations for, complications of, 180.

Adenosarcoma of left kidney in a young child, 417.

Adhesions of stomach and duodenum, 26.

Adrenals, see suprarenals.

Adrenalin, administered intravenously, 243; in blood during pregnancy, 1191, 1339; insufficiency as cause of death in chronic infections, 152.

Agglutination and precipitation in the early diagnosis of pulmonary tuberculosis, 925.

Air tract, upper, regional anatomy of, 594; upper, vasomotor disturbances of, 594.

Albuminuria, of adolescents in relation to life insurance, 130; of pregnancy, ocular troubles in, 208; simulation of, 836.

Alcohol, a depressant, 1178; and drug habitués, 1189; and life insurance, see insurance medicine; and pregnancy, 1258; and Wassermann reaction, 389; delusion as to value of, 147; mortality of, 1294.

Alcoholism, 488; a disease, 374; as a complicating factor of anesthesia, 669; chronic, 1189; lectures on, 436.

Alienists and neurologists, congress of, 1037.

Alimentary canal, obscure conditions of, as revealed by the *x*-rays, 98.

Alopecia, general, caused by fright or nervousness, 907.

Altitudes, high, physiological effects of, 24.

Alum baking powder, 587.

Am Ende, C., fluid extract of thyroids in epilepsy, 832.

Amberg, E., tympano-mastoiditis exhibiting mental symptoms, 477.

Amebiasis, intestinal, ipecac in, 1335; intestinal, treatment of, 97.

American Medical Association, 40, 76; election of honorary members, 92; election of officers, 92; general sessions; address of welcome, president's address, communication from Senator Owen, 44, 45, 46; house of delegates, 40; president's address, 40; prizes of, 80; report of board of trustees, 40; report of committee on Davis Memorial, 44; report of committee on memorial to officers who died during the Civil War, 43; report of committee on nomenclature and classification of diseases, 43; report of committee on national health organization, 43; report of committee on prevention of blindness, 41; report of committee on relief fund and physicians' sanatorium, 43; report of committee on scientific exhibit, 43; report of committee on scientific research, 43; report of committee on uniform regulation of membership, 41; report of committee on visual standards for pilots, 41; report of council on health and public instruction, 40; report of council on medical education, 42; report of director of postgraduate study, 41; report of general secretary, 40; report of reference committee on amendments to the constitution and by-laws, 44; report of reference committee on legislation and political action, 44; report of reference committee on medical education, 44; report of treasurer, 40; supplementary reports from reference committees, 92.

Amenorrhea, causation of, 18.

Anaphylaxis, 281, 488; a case of, 264; a Darwinian interpretation of, 309; and pneumococci, 292; and diphtheria antitoxin, 1335; and parturition, 490; atropine protecting against, 735; in carcinoma, 191; in human pathology, 539; intoxication from, 341.

Anaphylatoxins of bacteria, 142.

Anders, J. M., the climatic and hygienic influences of forest growth, 659.

Andresen, A. F. R., amebic dysentery, 1025.

Anemia, of nurslings, 887; pernicious, familial, 1214; pernicious, gastrointestinal tract in, 337; school, 289; secondary, effects on by hypodermic injections, 93; splenic, 1289; trophoneurotic, 192.

Anesthesia, 934; alcohol complicating, 669; choice of, 1240; don'ts, 1026; ether, 934; ether, by the open method, 887; in obstetrics, 28; infusion, 987; intratracheal insufflation, 934; intravenous and subcutaneous production of, 149; local, adjuvant to, 638; local, quinine and urea hydrochloride in, 768; methods of, 1091; nitrous oxide and oxygen, 934, 1289; nitrous-oxide-oxygen plus carbon dioxide, 786; pius pressure, 339; preceded by scopolamine, 788; quinine, in removal of tonsils, 813; rebreathing in, 1090; reform movement in, 27; spinal, 486, 987; spinal, in children, 499; trunk, caused by abscess of the brain, 1313; vomiting after, 87; warmed ether and chloroform in, 888; with exclusion of the four limbs, 485.

Aneurysm, abdominal, and its surgical treatment, 402; aortic, 242, 935; dissecting, of aorta and ruptured thoracic aneurysm, 605; intrathoracic, 1337; of innominate artery, 1332; treated by Abrams' method, 527.

Angiokeratoma, 787; of scrotum, 241.

Angioma, congenital cavernous, of neck, 726; nervous influences in causation of, 499; of uterus, bladder, and broad ligament, 843.

Anosmia, rare case of, 28.

Anthrax, incidence of, 583; prevention of, 1091; treated by Sclavo's serum, 293.

Antimony in typanosomiasis, 293.

Antiseptics, urethral, 338.

Antitrypsin, index of, 980.

Antrum, foreign bodies in, 595; sarcoma of, 202.

Anuria, calculous, 1048.

Anus, vestibularis, 194.

Aorta, aneurysm of, 242, 935; angusta, 30; regurgitation of, in young subjects, 28.

Aphasia versus anarthria, 989.

Aphonia, 1027; spastica, treatment, 689.

Apollyons, 786.

Apoplexy, slight strokes of, 1085; trephining for, 27.

Appendectomy and relief of symptoms, 190.
Appendicitis, a case of, 141; and rheumatism, 1085; chronic, 440; chronic, dilatation test for, 206; experimental, and rheumatism, 1031; fulminating, 638; in children, 141; lymphatic infection from, without peritonitis, 913; nonsuppurative subphrenic peritonitis complicating, 1343; operative treatment of, 421; retrocecal, 952; without physical signs, 402.
Appendix, abscess of, treatment, 100; abscess of, followed by phlebitis of the external jugular vein, 1278 absence of, 1040; and adnexa, 390; disease of, causing chronic invalidism, 1317; foreign bodies in, 835; hammock, 1129; primary sarcoma of, 340; inversion of, 340; strangulated, in a femoral hernia, 1336.
Apraxia, clinical tests for, 292.
Arm, gunshot wound of, 1336; paralysis of, due to nerve injuries, 365.
Armies, prevention of infectious diseases in, 231.
Army, maneuver division of, sanitary record of, 536; medical department of, in the field, 1230.
Arrhythmia, cardiac, strychnine in, 567.
Arsenionization in inoperable cancer, 707.
Arteries, coronary, diagnosis of sudden plugging of, 1190; hypertension of, the electrical treatment of, 866; hypertension of, treatment of, 1150; sclerosis of, see arteriosclerosis; pulmonary, embolism of, 390; pulmonary, ligation of branches of, in treatment of disease of lung, 289.
Arteriosclerosis, 624; and intestinal putrefaction, 636; d'Arsonvalization in treatment of, 1222; etiology of, 897, 1279; præcox, 232; treatment, 488.
Arthritis, acute influenzal, 329; chronic, 352; chronic polyarticular, 1250; deformans, treatment, 26, 1249; gonorrheal, vaccine treatment of, 1290; gonorrheal, iodine injections in, 442; influenzal, 27; rheumatic, vaccine therapy in, 868; rheumatoid, 1242; traumatic, in fractures of the arm, 506; treatment of, 935.
Arthrodesis in poliomyelitis, 607.
Arthroplasty, free, 1191.
Aspirin, poisoning by, 826.
Association of American Medical Colleges, report of delegates to, 602.
Astereognosis, permanent, uncomplicated, 383.
Asthma, 495; and nasal obstruction, 735; bronchial, eosinophilia in, 1241; bronchial, relation of coprostasis to, 089; endobronchial treatment of, 85.
Asphyxia neonatorum, 448.
Astigmatism, mixed, simulating brain tumor, 536; regular, operative treatment of, 1339.
Asylums, unlicensed, injunctions against, 1208.
Athletics and endurance, 330.

Boyce, J. W., foreign bodies in the lung simulating pleural effusion, 775.
Boyd, William A., quinine and urea hydrochloride; its preparation and its use as a local anesthetic, with a report of ten cases, 768.
Brain, abscess of, 872; abscess of, complicated by hysteria, and causing trunk anesthesia, 1313; abscess of, rhinogenous, recovery from, 1292; anatomy of, 643; cases in children, 108; extract of, combined with arsenic, in epilepsy, 442; hemorrhage of, treatment, 1151; metastases to the, 131; murmurs of, 936; organic and functional diseases of, 736; surgery of, 786; syphilis of, 1240; syphilis of defective memory in, 1188; the dog without a, 382; tumor, 338; tumors, diagnosis of, mixed astigmatism simulating, 536; tumor of prefontal lobe of, in criminals, 887; underfeeding as influencing growth, of 648.
Bread controversy, 634.
Breast, feeding, 638; tumors of, 201.
Brill's disease, 1221; symptom-complex, typhus and Manchurian typhus, 606.
British Medical Association, presidential address, 347.
Bromatotherapy, 147.
Bronchi, dilatation of, in small children, 280.
Bronchitis, fetid, lemons in, 858.
Bronchopneumonia, relieved by static wave current, 706.
Brooks, P. B., some observations regarding the control of measles, 1275.
Brown, John, and the brunonian system of medicine, 1115.
Bubo, inguinal, 1288.
Buck, A. H., ipecac in dysentery and typhoid fever, 1136.
Bulkley, L. D., ipecac in dysentery and typhoid fever, 1236.
Burch, J. H., the electrical treatment of arterial hypertension, 866.
Burma, the medical uplift in, 603.
Burning, death from, local and general changes associated with, 291.
Burns, skin grafting for, 487.
Bursitis, subdeltoid or subacromial, mistaken for brachial neuritis, 707.
Butter, certified and pasteurized, 441.

C.

Calcium sulphide, 305.
Calculus, salivary, of Wharton's duct, 1227.
California, climate of, 879; southern, as a winter resort, 1138.
Cancer, 387, 441, 522; and its treatment, 1153; and products of fetal autolysis, 1041; cell, 1229; commission on, 1098; colloidal nitrogen in the urine of, 1306; diagnosis of, new methods in, 431; "en cuirasse," 441; factor of commonness in the diagnosis of, 1141; immunity in, 230; immunization, 242; inoperable, arsenionization in, 707; methylene blue urinary reaction in, 86; methylene blue test in urine of, 876; mortality of, reduction of, 1289; neoformans vaccine in, 1075; non-operative treatment of, 289; of digestive tract, treated with radium, 609; of nasopharynx, 1041; of orbit, treated with *x*-ray, 406; of stomach, chemical and biological aids in the early diagnosis of, 371; of tongue, tonsil, and pharynx, 139; of trees, 487; of uterus, 50; personal observations on, 1003; problem of, 896; postoperative röntgenization in, 846; radium treatment of, 1338; rôle of fat in etiology of, 27; stage preceding, 1026; statistics, 1289; statistics from Baden, 1143; sunlight in after-treatment of, 581; surgery of, 340; treatment of, 1143; treatment of following operation, 486; vaccine treatment of, 1188; Wassermann reaction in relation to, 141.
Capsule, inner, sensory tract in relation to, 646.
Carbohydrate, feeding in typhoid fever, 1174; tolerance of, and the hypophysis, 479.
Carbon dioxide, inhalations of, 496; snow, 242; snow in trachoma, 294.
Carbuncle, 141.
Carcinoma, anaphylaxis, 191; formation in bones secondary to growth in some epithelial organ, 847; human, viability of in animals, 835; of bone, 1240; of clitoris, 49; of larynx, 192; of parotid, Coley's fluid in, 87; of rectum, 140, 204; partial gastrectomy for, 942; pregnancy predisposing to, 30; the hemolytic skin reaction in, 337.
Cardiomyophathies, 927.
Cardiospasm in infancy, 172, 221.
Cardiovascular disease, rational treatment of, 706; degenerating, 293.
Caries, "comforter," 1141.
Carlsbad treatment of stomach disease, 1304.
Carter, W. W., the correction of nasal deformities by mechanical means and by the transplantation of bone, 1159.
Cases, report of, 1172.
Catarrh, vernal, cosinophile cells in, 835.
Cataract, extraction of, 241, 390; operations, 1240; traumatic, 241.
Cautery, effect of, on tuberculous lesions, 600.
Cecum, fixation of, 289; movable, and typhlotomy, 766.
Cell oxidases, function of, 1328.
Cerebritis with effusion, 1205.
Cervix, recent repair of, 325; anteflexion of, and spasm of uterine ligaments in relation to retroversion, dysmenorrhea, and sterility, 802.
Cervicitis and endometritis, gonorrheal, 921.
Cesarean section, 106, 901, 1001; and results of, 85; history of, 85; immediate results of, 85; improved technique of, 1191; technique of, 85; vaginal, in eclampsia, 802.
Ceylon, sanitary matters in, 239.
Chalk paste, 338.
Chancres from kissing, 586.
Chapin, H. D. Christian Science in operation, 1264.
Cheese, food value of, 878.
Chemistry and medicine, 88.
Chemotherapy of pneumococcus infection, 587.
Child, Christian Scientist's cruelty to, 282; father's duty to furnish medical attendance to, 908; height and

weight of, in England, 88; nervous, management of, 951; state guidance of, 85.
"Chiropractic," adjustment in treatment, 756; must be licensed, 756.
Chisels for making bone flaps, 986.
Chloretone in seasickness 141.
Cholecystitis, and cholelithiasis in relation to pregnancy, 106; frequency and etiology of, 1095; medical treatment of, 1095; pathology and complications of, 1049; surgical treatment of, 1095; symptomatology and diagnosis of, 1095; typhoid bacillus, 440; without stone, 195.
Cholelithiasis and chronic pancreatitis, 140.
Cholera, at Palermo, 1242; epidemics in Russia, 369; protection against, 885.
Chondrodystrophy, a case of, 1301.
Chorea, acute, 904; nature and treatment of, 232.
Chorioepithelioma malignum, 615.
Christian Science, cruelty of, to children 282; in operation, 1264.
Chromaffin system, exhaustion of, 132.
Chylangiomata, a case of, 676.
Circulation, disorders of, treatment, 1038; effects of passive motion on, 539; failing, management of, 1039; progress in knowledge of, 300,
Climacteric, senile, 1240.
Climate of California, 879.
Clitoris, carcinoma of, 50.
Clothing and regulation of body temperature, 140.
Cockroach, bacteriology of, 1338.
Cocks, G. H., the radical frontal sinus operations, 6.
Coffee, modified, 690; use and abuse of, 388.
Coleman, J., an improved submucous knife, 1029.
Coley toxins in leucemia, 152; in parotid carcinoma, 87; in sarcoma, 190.
Colon, and ileum, extensive excision of, 787; bacillus, diseases produced by, 1045; bacillus infection of lungs, 1147; bacillus infection of the urinary passages, 709, 1042; cancer of, 785; chronic intoxication from, 1152; disease of, causing chronic invalidism, 1317; indigestion, 496; irrigation, the long or short tube in, 501; transverse infarct of, 339.
Communications, privileged, 907.
Compensation, enforced, 705.
Conjunctivitis, ichthyotoxic, 442; epidemic of, 1141.
Constipation, habitual, and the urinary organs, 1190; simulating appendicitis 690; spastic, objective findings in, 1293; treatment of, 706, 736.
Consultation, what constitutes a, 408.
Contagion, control of, 886.
Cook, H. W., blood-pressure in prognosis, 959.
Corbus, B. C., one year's experience with salvarsan, being a report of 230 injections with special reference to eye and ear complications, 1009.
Cord, twisting of, *in utero*, 441.
Corporation, attitude of, to its injured employees, 62.
Corpora quadrigemina, tumors of, 645.
Cornea, ulcers of, 537.
Cornwall E. E., clinical notes on chronic putrefaction toxemia of intestinal origin, 1269.
Correspondence: Berlin, 288, 336, 584, 783, 1087; Canada, 200, 534, 784, 1086; Copenhagen, 933; London, 135, 187, 235, 286, 334, 386, 437, 484, 582, 634, 683, 732, 782, 883, 931, 982, 1035, 1084, 1137, 1186, 1236, 1233; Paris, 237, 287, 485, 1037, 1236; Philippines, 239; Vienna, 289; 438, 486.

Dermatology, progress of, 27.
Dermatoses, toxic, 703.
Detubation difficulties, after diphtheria, 690.
Diabetes, acidosis of, rectal infusion of sugar solutions in, 587; and adrenalinemia, 988; and glycosuria, causal therapy of, 244; bronzed, 200; classification of, 388; common errors in treatment of, 571; deafness in, 25; from a surgical standpoint, 150; in a seven-months-old baby, 450; insipidus, 828; insipidus, metabolism in, 1188; magnesium superoxide in, 738; modern treatment of, 163; pancreas feeding in, 139; pancreas, therapy of, 243; treatment of, 97; mellitus, treatment of, 835, 1040, 1090; refraction changes in, 441; wheat flour treatment of, 244.
Diagnosis, exploratory, 291; perplexing, two cases of, 1196; the Odyssey of a, 1165.
Diaphragm, enteroptosis and altered function of, 1335.
Diarrhea, epidemic summer, 737; infantile, hypertonic salines in, 1243; summer, 241; treatment of, 1123, 1147; uzara in, 888.
Diastase excretion in the urine, diagnostic significance of, 1293.
Diathermia, 332; from high frequency currents in gonorrheal arthritis, gout, and rheumatism, 289.
Diet, card, 884; in acute infectious diseases, 26; in nephritis, 1041; Lenhartz, in treatment, 1328; quantitative regulation of, 94.
Digalen, physiological action of, 1242.
Digitalis, 1151; as afforded by gastric secretions, 1039; chemistry of, 837; in heart disease, 241.
Dilatation test for chronic appendicitis, 206.
Diphtheria, 1298; antitoxin administered by the mouth, 294; antitoxin and anaphylaxis, 1335; blood pressure in, 1215; carriers, staphylococcus spray in, 986; difficult detubation after, 690; of wounds, 585; progress in treatment of, 1142; toxin, demonstration of, in the blood, 1292; treatment of, 738.
Disease, antagonism of, 737; chronic, treatment of, 151; infectious, a premonitory sign of, 1132; social measures in fighting, 23; relative frequency of, in Boston, 388; systemic, treatment of portal of entry of, 885.
Disinfection of hands and operative field, 288.
Disinfectants, phenol coefficient of, 1091.
Dislocation, occipitoatlas and atloaxis, 735.
Doty, Dr., a professional endorsement of, 1235; the attack on, 1180.
Douche therapy, 1191.
Drill and development, 1091.
Drought and sanitation, 728.
Drueck, C. J., perirectal abscess, 376.
Drugs, idiosyncracy to, 837; proprietary, 835.
Dukeman, W. H., chorioepithelioma malignum, report of a case following abortion; ovaries retained; complete recovery; with detailed report of the pathologist, 615.
Duncan, C. H., a new method of vaccine treatment and prevention of sepsis, 567.
Duodenum, acute inflammation of, in children, 1200; congenital atresia of, 836; diseases of, diagnosed by the *x*-ray, 847; infection of, treatment of, 706; phlegmonous inflammation of, 339; tube for, 390;

tube for, for infants, 805; ulcer of, 405, 686; ulcer of, in early life, 2501.
Dura, endothelioma of, 1039.
Dust, menace of, and municipal diseases, 699.
Dyschondraplasia, 506.
Dyschromatopsia, in brain tumor, 241.
Dysentery, amebic, 1024; chronic non-amebic, 714; spirillar, 85.
Dysmenorrhea, and sterility, Dudley's operation for, 1197; due to small fibroids, 450; relieved by nasal treatment, 802.
Dyspepsia, anemic enteroptotic, treatment of, 666; in nurslings, importance of analysis of mother's milk in, 258; neurotic, 1338.
Dyspituitarism, 905.
Dystocia from echinococcus of the female pelvic organs, 307.
Dystrophia adiposogenitalis, 989.

E.

Ear, bacteriology of, 935; diseases of, in the exanthemata, 935; diseases of, in relation to those of the eyes, 786; middle, and mastoid inflammations, 936; middle, primary sarcoma of, and of mastoid, 1089; traumatic lesions of, 1050.
Eccles, R. G., a Darwinian interpretation of anaphylaxis, 309.
Eclampsia, 1141; a case of, 688; cause and cure of, 450; in a girl of twelve, 448; nature and treatment of, 989; vaginal cesarean section in, 802.
Ectropion, 1140.
Eczema, infantile, altitude in treatment of, 533.
Edema, familial angioneurotic, fatal, 1293; non-renal, as a familial affection, 339.
Education, medical, 488, 1041; medical, high standard in, 300; medical, latest improvement in, prevention, 601; medical, report of conference of American Medical Association, 602.
Ehrenreich, S., scrofula, 219
Einhorn, M., on the value of radium treatment in cancer of the digestive tract, 609.
Einhorn's disease, autopsy findings in a case of, 47.
Elbow-joint, injuries to, 736.
Elder, O. F., a brief report on 414 injections of salvarsan, 1126.
Electricity, a rational muffler for high frequency spark of, 706; diathermia from high frequency currents of, 289; direct continuous currents of, 705; high frequency currents of, in therapeutics, 706; high potential currents of, 705; in arterial hypertension, 865; in gastrotherapeutics, 706; induced currents of, 705; static, in nervous and mental diseases, 706; static currents of, 705.
Electrocardiograph, 547.
Electrocution, burns of cranium after, 485.
Electrotherapy, 192.
Elephantiasis, non-parasitica, 211; of the vulva, tuberculous, 450; sporadic, 1090.
Elimination, 706.
Embolism, fat, 1031; pulmonary, 390.
Emotion, physical manifestations of, 1178.
Emphysema, cutaneous during labor, 292; subcutaneous, 496; surgical treatment of, 638.
Empyema, a new method of treatment of, in young children, 816; decortication of the lung for old, 51; treatment of, 685.
Encephalitis following injection of salvarsan, 588.
Endocarditis, acute, 987; experimental influenzal, 122; infective, 87; malignant, in New York City, 109, 152.
Endoaneurysmorrhaphy, 293.
Endothelioma of omentum, 86.
Endowments, workingmen's, 527.
Endurance and athletics, 330.
Enteritis, epidemics of, synchronous with cycles of solar activity, 46.
Enteroptosis, 1205; and altered function of the diaphragm, 1335; in children, 48.
Enuresis nocturna and spina bifida occulta, 244; thyroid extract in, 1337.
Enzyme, action, the nature of, 396; digestive action of H_2O_2 on, 1042.
Eosinophiles, in vernal catarrh, 835.
Eosinophilia in bronchial asthma, 1241.
Epidemics, of pneumonia, grippe, and enteritis synchronous with cycles of solar activity, 46.
Epididymis, section of, 1039; tuberculosis of, 1335.
Epigastrium, habitual protrusion of, 1336.
Epiglottis, suture of, 1283.
Epilepsy, and pregnancy, 803; and the epileptic temperament, 261; Brown Séquard's in guinea pigs, 984; compounds of bromides and urea in, 888; crotalin treatment of, 636; dental defects, as cause of, 947; fluid extract of thyroids in, 832; idiopathic methods of curing, 906; new methods of treating, 690; researches, 956; signs of organic lesions in, 977; surgical treatment of, 835; treated with extract of brain and arsenic, 442; treatment of, 318.
Epithelioma, irritation as cause of, 1089.
Epithelium, conductors and obstructors of, 150.
Epstein, S, flat-foot in women and children, 222.
Equinovarus, treatment of relapsed cases of, 504.
Eruptions, ringed, in diseases of skin, 55.
Erythema, multiforme, toxic origin of, 704; nodosum syphiliticum, 702.
Eshner, A. A., typhoid fever with relapse and multiple complications, 1021.
Esophagoscope, 1140; in esophageal surgery, 685.
Esophagoscopy and bronchoscopy by the Killian method, 597.
Esophagus, congenital web of, 600; dilator and sound for, 338; surgery of, esophagoscope in, 685.
Esthiomène and secondary elephantiasis vulvæ, 1196.
Ether, drop method of administering, 1077; rausch, 141.
Ethmoid, cells, indications for opening and evacuating, 690; disease as related to orbital conditions, 1101.
Eugenics, 601.
Evidence, admissible, of failure to attend accouchement as promised, 557; of medical expert as to injuries showing bias, 557; opinion, 1307; proving existence of nervous disease, 557; refreshing recollection, 408.
Ewing, J., the public and the medical profession, 1209.
Examination, medical, evidence as to, made through interpreter, admissible, 208.
Exanthemata, aural complications of, 935.
Exercise, and blood-pressure, 699; need of by school-girls, 1078.
Experiment, method of, 735.
Exophthalmic goiter, 288; disease of chromaffin system in, 487; in a boy of ten, 1077; nucleoproteid of the thyroid colloid in treatment of, 1293; relation of to pelvic disease, 51; symptoms of, as a sign of tubersulosis, 677; treated with the milk of thyroidless goats, 1337; vomiting in, 1241.
Exophthalmos in nephritis, 1139.
Expert, evidence, admissible to show that homicide could not have been suicidal, 756; medical, competency as, 908; medical, qualifications of, 658; medical, qualification of, to testify as to electricity's powers to kill, 657; medical, reading medical works to, 407.
Eye, adjustments of, and pose of body, 585; conjugate of, and fusion brain centers, 389; constitutional remedies in affections of, 928; contusions of, and mental symptoms, 1088; diseases of, in relation to those of the ear, 786; foreign body in, 302; malformations of, 490; nervous affections and adjustments of, 786; pus in anterior chamber of, 141; shortening of muscle of by tucking, 389; syphilitic affections of, 879; tumors of, 241.
Eyelids, plastic surgery of, 292

F.

Face, plastic surgery of, 536.
Fallopian tube, primary carcinoma of, 105.
Farnsworth, C. P., a case of chylangiomata, 676.
Fat, digestion of, in infants, relation of gastric to pancreatic, 107; tissue, water content of, 1264
Fear, significance of, in mental diseases, 123.
Fee, contract for, contingent on damages recovered by invalid, 558.
Feebleminded, care and training of, 904.
Feeding, infant, 107; infant, malt sugar and high percentages of casein in, 502; of sick infants, 55.
Felberbaum, D., the albumin reaction of the sputum in pulmonary tuberculosis, 870.
Femur, cyst of upper end of, simulating hip disease, 350; fractures of, 414, 1098; malformation of, 989.
Fermentation diseases, 1179.
Fetus thoracopagus, 605.
Fever, alimentary, in adults, 937; estival, etiology of, 958; following intravenous injections, 1292; in tuberculosis, 47; obscure cases of, without physical signs, 496; significance of, 1191.
Fibrillation, auricular, 937.
Fibroids, and thyroid, 241; cervical, 999; uterine, axial rotation of, 987; uterine, blood supply of, 830; uterine, dangers of, in advanced life, 450; uterine, death from, 242; uterine, electrical treatment of, 677; uterine, ovarian hormone as cause of growth of, 142; uterine, relation of to sterility, 1239; uterine, small, causing dysmenorrhea, 450; uterine, strangulation by torsion of the pedicle, 676; uterine, torsion of, complicating

pregnancy, 50; uterine, torsion of pedicle of, 293; uterine, treatment of, 104; uterine, *x*-ray treatment of, 341.
Fibroma, nasopharyngeal, 596.
Fibrositis as cause of chronic hypertrophic spondylitis, 25.
Finger, gangrene of, 488; phenomenon, 1089.
Finlay, work of, on yellow fever, 285.
Fishberg, M., the albumin reaction of the sputum in pulmonary tuberculosis, 870.
Fischer, C. S., a practical consideration of hyperchlorhydria and hypersecretion, 821; remarks upon hyperchlorhydria and chronic dyspepsia, 115; what constitutes hyperchlorhydria? 469.

McMurtrie, D. C., the care of the crippled and rachitic in Italy, 1218.
Mears, J. E., the triumph of American medicine in the construction of the Panama canal, 409.
Measles, associated with scarlatina, 673; control of, 1275; direct contagion of, 1232; experimental, in the monkey, 182, 389; experimental, leucocytosis in, 1241; infectivity of scales and secretions of, 1090; or rubella, 300; seriousness of, 1328; virus of, 687.
Meat, broths, value of, 535; ingestion of, in relation to indicanuria in infants, 105.
Mediastinum, and cough, 688; enlarged glands of, value of "Eustace Smith" bruit in, 498; glands of, 687; malignant lymphocytoma of, 190.
Medical society, act incorporating, 207.
Medicine, American, in the construction of the Panama Canal, 409; aims in, 488; and surgery, practising, definition of, 108; as a profession 937; chemistry and, 88; dropper clip, 1189; history of, rewriting the, 1327; masters of, and medical ideals, 717; postgraduate courses in, 603; practice of, certificate for, not required of vendors of drugs, 557; practice of, mistakes in, 380; practice of, reminiscences of, 834; practice of, unlawful, 558; practice of, without drugs, 1307; practising, masseur treatment is, 408; preventive, 27, 137, 1239; profession of, and the public, 1209; profession of, changes of, in forty years, 304; profession of, influence of, 242; progress in practice of, 734; reminiscences in practice of, 734; social questions from viewpoint of, 1241; specialism in, 809; statistical method in, 145, student of, and his books, 827; suggestion in practice of, 535; teaching preventive, in universities and normal schools, 601; tendencies in, 1006; two degrees in, 603; Western, education of Chinese in, 603.
Mediocrity in medical profession, 602.
Megacolon, 100.
Meigs, A. V., the quantitative analysis of human and cows' milk, 1309.
Melanoblastomata, 587.
Melanuria without melanotic tumor, 20.
Membranes, sterilized animal, in surgery, 1003.
Memory, defective, in brain syphilis, 1188.
Ménière's disease, operation for, 27.
Meningitis, and malaria, 934; and vivisection, 292; cerebrospinal, 241, 1155; diagnosis of, 750; epidemiology and treatment of, 777; following measles, 537; influenzal, serum treatment of, 131; pneumococcus, 388; purulent labyrinthic, 195; tuberculous, 427, 637.
Meningoencephalitis, rhinogenous traumatic, 989.
Menorrhagia in virgins, 204.
Menstruation, absence of ovulation in, 74.
Mercuric chloride poisoning, 389.
Mercury, in syphilis, 292; poisoning, acute, 390; succinimide in treatment of tuberculosis and other vegetable parasitic diseases, 1109.
Mesentery, fibromatous tumors of, 402; tuberculous glands of, and some abdominal conditions they may give rise to, 402; tumors of, 102.
Mesothorium, emanation action of, 1243.
Metabolism, in nervous diseases, 829; nuclein, 331.
Metatarsalgia, 258.
Methylene blue, test in urine of cancer patients, 876; urinary reaction in cancer, 86.
Micrococcus, a, in a resistant dermatosis resembling acne vulgaris, 703.
Midbrain, lesions of, some obscure tumors due to, 645.
Migraine, phosphorus and lecithin in the treatment of, 79.
Mikulicz's disease, 502.
Milk, albumin, 1336; condensed, 733; depots, in reduction of infant mortality, 629; feeding after first year, disturbances arising from, 499; municipal supply of, 895; pasteurization of, in the bottle on a commercial scale, 111; percentage, a new method of calculating, 501; quantitative analysis of human and cows', 1309; question, 189; relation of, to public health, 895; routine examination of, 337; top, for infant feeding, 118; tubercle bacilli in, 752; whole and fat-diminished, in infant feeding, 1138.
Mind, beginnings of, in the newborn, 77; development of, in children, 143; expert opinion as to condition of, 908.
Mineralization in the treatment of pulmonary tuberculosis, 1236.
Mining, coal, explosives in, 27.
Miscarriage, treatment of, 84.
Missions, medical, in Korea; medical, necessity for trained workers in, 603.
Mistakes in medical practice, 347, 380.
Mistletoe, 637.
Mitchell, J. R., the limelight on pneumonia, 264.
Mitral valve, stenosis of, 989.
Molar, lower elevation of, 1243.
Monstrosity, 487.
Morgan, W. G., cardiospasm in infants, 172.
Morphine, infantile tolerance toward, 434.
Morphinism, treatment of, 496.
Morris, R. T., wasp-stings and influenza, 831.
Mortality, cancer, reduction of, 1289; infant, influence of milk station work on, 848; infant, reduction of, 849; influence of anesthetics on, 998; monthly, 1089.
Moschcowitz, A. V., the question of transplantation of the cord in operations for hernia, with a note on the rôle of the transversalis fascia in the production of abdominal hernia, 1319.
Mosquito, toxin of, 837.
Mothers, nursing, premiums for, and milk depots for infants, 805.
Mouth gag and tongue depressor, 734.
Mulot, O. L., the significance of relapses, 673.
Murmur, interpretation of, 889; intracranial, 936; presystolic, the mechanism of the, 2.
Muscle, atrophy of, traumatic, 530; rectus, rupture of, 587.
Mushroom poisoning, 630.
Music in therapeutics, 786.
Mutation, phenomena in bacteria, 442.
Myelitis, compression, 439.
Myocardium, treatment of, 1039.
Myopia, in school children, 338; operations for, 689; surgery of, 1188.
Myotonia atrophica, 787.

N.

Narcolepsy, essential, 381; in glandular affections, 558.
Narcosis, nature of, 926.
Narcotic habitués, acute ailments in, 686.
Nascher, I. L., the strenuous life, 722.
Nasopharynx, cancer of, 1040; fibroma of, 596; prophylaxis of, 824.
Nauheim treatment of heart disease, 695; compared with that in America, 1304.
Necator americanus, 338.
Neck, congenital cavernous angioma of, 726; lymphomata of, 523; malignant lymphoma of, 727; woody phlegmon of, 338.
Needle, holder, 537; to carry a single strand of suture, 301.
Nelson, W. H., some experiences with "Russo's typhoid-fever test," 373.
Neoformans vaccine in cancer, 1075.
Nephrectomy, pregnancy after, 183.
Nephritis, acute, in children, blood pressure in, 172; and uremia, nitrogen retention in, 183; chronic, decapsulation of kidney for, 57; chronic, reserve renal capacity in, 93; diet in, 1041; exophthalmos in, 1139; following parotitis, 650; scarlatinal, 1293; surgical treatment of, 679.
Nephropexy in relief of hematuria, 1241.
Nephroptosis, effect of, on nervous system, 1206.
Nerve, anastomosis, 193; fifth, function of, 141; fifth, regeneration of the drusory root of, 644; metabolism in diseases of, 829; pressure massage and action on, 988; roots, posterior spinal, resection of, 242; suture of, 26; trophic, 183.
Nervous system, central, metastatic growths of, 140; central, senile affections of, 443; diseases of, 166; diseases of, early signs and symptoms of, 1337; syphilis and parasyphilis of, 1193; syphilis of, combinations of arsenic and mercury in, 194; syphilis of, irregular course of, 194.
Neuhof, H., some methods of physical examination in the diagnosis of surgical diseases of the kidney, 127.
Neuralgia, trifacial, alcohol injection in, 140.
Neurasthenia, and its treatment by electricity, 707; the x-rays in, 947.

Neuritis, familial hypertrophic, 29; hot-air douche in, 73; multiple, with twelfth nerve paralysis, 1336; optic, 388; optic, after injection of salvarsan, 1338.
Neurology, laboratory findings in, 292.
Neuroses, and neuritides, occupation, 647; traumatic, in the United States, 646.
Neustaedter, M., two cases of Little's disease, 613.
New Orleans and the Panama Canal, 1230.
New York Medical Journal, new editor of, 1232.
Newton, R. C., John Brown, M.D., and the Brunonian system of medicine, 1115.

Obstetrics, advances in, 799; and gynecology, problems of, 936; and gynecology, vaccines in, 105; anesthesia in, 28; duty in, 1154; in general practice, 25; standard of degree of care in, 756.
O'Dwyer, J., the O'Dwyer forcible respiration apparatus for children, 576.
Ohlbaum, J., a case of missed abortion, 430.
Olesen, R., the band at the Culion Leper Colony, 84.
Omentum, endothelioma, of, 86; great, torsion of, 1141; functions and surgical uses of, 401; lymphangiomata and cysts of, 102.
Operations, how long should patient remain in bed after, 999; technique of, 1004.
Ophthalmia, neonatorum, intrauterine, 886; neonatorum, popular misconceptions regarding, 913; nongonococcic, 1228; purulent, 191; sympathetic, 88.
Opticians, relation of medical profession to, 55.
Optometry, 292.
Orbit, conditions of, as related to ethmoid disease, 1101; disease of, secondary to sinusitis, 1101; cancer of, treated with *x*-ray, 406.
Oropharynx and nasopharynx, prophylaxis of, 824.
Orthodiascope, in diagnosis, 1248.
Orthopedics, standardization in instruction of, 348.
Os calcis, spur formation on, 507.
Osmosis and nasal vasomotor phenomena, 985.
Osteitis deformans, 776.
Osteoarthropathy, hypertrophic pulmonary, 1247.
Osteomalacia, the treatment of, with hypophysis extract, 439.
Osteoperiostitis, gonorrheal, 100.
Otitis, media, acute, 985; media, and climate, 440; media, and nose, and throat, 440; media, from "comforter," 688; purulent, influence of Eustachian tube on, 1100.
Otology, aids to diagnosis in, 1099.
Ovariotomy and cesarean section, 390.
Ovary, behavior of, after removal of uterus, 801; biological studies in, 25; conservation of, 800; cyst of, 886; cystic, 887; double dermoids of, in pregnancy, 799; internal secretion of, 677, 800; left, after hysterectomy, 801; papillomatous cyst of, causing pulmonary metastases, 950; study of function of, by unilateral castration, 876; substance of, clinical researches with, 195; torsion of pedicle of cyst of, 514; transplantation of, in lower animals, 801.
Ovulation and menstruation, chronological relations, 280; without menstruation, 74.
Oxidoses, cellular, function of, 1328.
Oxypathy and uric acid, 499.
Ozone, inhalations for pertussis, 341.

P.

Pachymeningitis, hemorrhagica interna in infants, 539; spinal, chronic hypertrophic, 644.
Paget's disease, a case of, 214.
Pain, abdominal, from spinal curvature, 388; opinion as to continuance of, from injury, 907; upper abdominal, 1152.
Palate, cleft, treatment of, 402, 1241.
Palpation, 1188.
Panama Canal, and New Orleans, 1230; sanitary menace of, 1280.
Pancreas, accessory, 787; cyst of, 538; diagnosis of disease of, 441; feeding in diabetes, 139; therapy of diabetes, 243.

Pancreatitis, acute, 1339; acute hemorrhagic, 1344; chronic, and carcinoma of the pancreas, 339; chronic, and gallstone disease, 140; etiology and treatment, 950.
Papillæ of Morgagni, hypertrophied, 242.
Parabiosis and xiphopagi, 283.
Paralysis, agitans, 1143; agitans, larynx in, 737; arm, painful of children, 1243; brachial, 51; exercise treatment of, 503; general, see paresis; in cirrhosis of the liver, 486; postdiphtheritic, Sarat's method of treatment of, 329; residual, following poliomyelitis, use of intra-articular silk ligaments in loose joints of, 352; spastic, muscle-group isolation in treatment of, 352; third nerve recurrent, 1101; Volkmann's ischemic, treated by method of Robert Jones, 503.
Paranoia, psychological mechanisms of, 1335.
Paraplegia, Pott's, lanimectomy for, 507.
Parasites, animal, remedies for, 786.
Paratyphoid infections, 382.
Paresis, early symptoms of, 650; Wassermann reaction in, 1141.
Parker, G., the healed tuberculous lesion from a life insurance standpoint, 915.
Parotid, Coley's fluid in carcinoma of, 87; painless swelling of, 836.
Parotitis, 200.
Parturition and anaphylaxis, 400.
Patients, of moderate means, 528; printed instructions for, 976; surgical, after-care of, 1098.
Pavor nocturnus, 1177.
Peckham, C. F., the treatment of anemic enteroptotic dyspepsia, 666.
Pedersen, J., clinical observations in some cases of prostatic obstruction, 69.
Pedersen, V. C., adenosarcoma of the left kidney in a young child; Langenbuch's nephrectomy; recovery, 417.
Pediatrics, fundamental principles of, 249; service of, in Presbyterian Hospital, 750.
Pediatrists, opportunities of, 48.
Pellagra, 1140, 1152; and diet, 1140; and salvarsan, 1140; cacodylate of soda in, 536; dietetic management of, 986; epidemiology of, 1045, 1079; in Philadelphia, 209; mental stress a factor in, 1128; salvarsan in, 27; in fowls, 1140; treated by high potential current, 707; treatment of, 1154.
Pelvis, contracted, 708; funnel, 797; infections of, operative period and drainage in, 105; malignant disease of organs of, 787; organs of, useless removal of, 104; perpendicular, 338.
Pepsin, urinary, in gastric diseases, 341.
Pepys, Samuel, astigmatism of, 141.
Pericardium, massive effusion of, 946; prevention of adherent, 294.
Perihepatitis, universal chronic, treatment of, 151.
Perineum, preliminary suture of, 235; secondary repair of, 997.
Peristalsis, hormone for, 78.
Peritoneum, grasping forceps, 637; sensibility of, 536; tuberculosis of, 202.
Peritonitis, biological treatment of, 789; diffuse septic, 1040; general, 1207; general suppurative, postoperative treatment of, 943; nonsuppurative subphrenic, complicating appendicitis, 1343; treatment of general septic, 397; tuberculous, 497, 545.
Peroneus, spasm of, 506.
Perspiration, excessive local, 489.
Pertussis, abortive, 776; and spasmophilia, 508; unexpected dangers of, 1077; vaccine in, 402.
Petit mal, narcoleptic, 381.
Pfannenstill method of treating lupus of the nasal mucous membrane, 933.
Pharmacopœia and practice of medicine, 1139.
Pharynx and esophagus, tooth-plate in, 242.
Phenolsulphonephthalein as a test of renal function, 748, 1248.
Phlebitis of external jugular vein following appendicular abscess, 1278.
Phlegmon, woody, of Reclus, 1189.
Phosphaturia, 230, 243.
Phosphoric acid elimination, daily cycle of, 1283.
Photomicrographs, colored, 1038; in natural colors, 729, 831.
Phototherapy, 705.
Physician, and health department, 687; and the people, 1096; annuity insurance for, 78.
Physicotherapy, attitude of the medical profession toward, 707; standardization of, 706.
Physiology, clinical, 637.
Pigmentation, multiple areas of, 705.
Pilcher, J. T., chronic invalidism due to pathological conditions of the colon and appendix, 1317.
Pin, swallowed, history of, 537.
Pituitary body, see hypophysis.
Pituitrin, as an oxytocic, 489, 1339; in obstetrics, 489.
Placenta, cervical implantation of, and rupture of the uterus, 886; previa, 338; previa, analysis of, 795; previa, treatment of, 794, 795, 796; retention of, from premature use of ergot, 789.
Plague, bubonic, of ground squirrel origin, 97, 886; causes of, 684; control of, 886; pneumonic, 886; prevention and eradication of, 1045; treatment of, 1091.
Platinum, colloidal action of, on blood in myelogenous leucemia, 509.
Plaut-Vincent angina microorganism, specificity of, 195.
Pleura, accidents from exploratory puncture of, 995; effusions of, gaseous injections in treatment of, 1029; effusion of, mechanical effects of, 1041.
Pleurisy, and empyema as complications of pneumonia, 94; treatment of, 980.
Pneumectomy, experimental, 337.
Pneumococcus, serum against, 86; infection, chemotherapy of, 587, 1042.
Pneumohypoderma, 1062.
Pneumonia, acute dilatation of the stomach in, 1280; antenatal, 1141; atypical, 608; bloodletting in, 229; blood pressure in, 93; epidemics synchronous with cycles of solar activity, 46; Friedländer, 1339; leucocytes in, 698; lobar, heart stimulation in treatment of, 946; mania following, 496; pleurisy and empyema as complications of, 94; secondary, and its treatment, 893; septic, caused by a hat pin, 737; and sudden loss of weight, 997; the limelight on, 264; treatment of, 789.
Pneumonocomosis in stonecutters, 890.
Pneumothorax, 242; artificial, in treatment of pulmonary tuberculosis, 1041; artificial, in treatment of tuberculosis and hemoptysis, 293; in pulmonary echinococcus, 490; in pulmonary tuberculosis, 619.
Poisoning, veronal, 705.
Polioencephalomyelitis, meningitic forms of, 86.
Poliomyelitis, 141, 188, 451, 481, 898, 1091, 1140, 1291, 1299; abortive, 129; and guinea-pig paralysis, 195; and infantile scurvy, 190; arthodesis in, 607; cerebral type, 451; cerebrospinal fluid in, 1190; control of, 886; epidemics of, prevention of, 259; epidemology of, 499; experimental work on, 452; in an adult, 736; in Massachusetts, 99; in Missouri, 351; in Pennsylvania, 98; intraarticular silk limaments for loose joints in, 352; nomenclature of, 1289; Pennsylvania's work on, 945; prognosis in, 834; propagated by dust, 734; spinal type, 451; surgical treatment of, 945; syphilitic, in adults, 294; transmitted by dust, 934; treatment of, 28, 452, 707; treatment of, with recumbency and immobilization, 143; torticollis following, 788.
Pollen, vaccine, in hay fever, 736.
Polygraph as aid to diagnosis of cardiac affections of children, 404.
Polygraphy, clinical, 546.
Polyserositis, chronic, pathogenesis of, 588.
Pons, tumor of, 947.
Popliteal artery and vein, rupture of, 1190.
Postnasal catarrh in children, 1040.
Postoperative complications, 105; treatment, 935.
Potassium chlorate poisoning, 587.
Potter, A., a preliminary report on the use of neoformans vaccine in the treatment of cancer, 1075.
Pott's disease, bone transplantation in, 638.
Practice, lodge, 894.
Precocity, intellectual, 579.
Pregnancy, acetonuria in, 789; after nephrectomy, 183; albuminuria of, ocular troubles in, 208; alcohol and, 1258; and epilepsy, 803; and heart disease, 1338; artificial termination of, 988; bilateral tubal, 1207; cholecystitis and cholelithiasis in relation to, 106; complicated by scarlet fever, 686; complicated by ovarian and uterine tumors, 207; complicated by torsion of fibroid, 50; double dermoids in, 799; early months of, 199; ectopic, 574; ectopic, early diagnosis of, 1000; ectopic, full term, 1188; ectopic, repeated, 803; interstitial, 1000; pernicious vomiting of, 105; position in, *x*-ray diagnosis of, 950; predisposing to carcinoma, 30; salpingostomy in, 798; serodiagnosis of, 30; toxemia of, and hemorrhage, 88; toxemia of, 828; twin, in uterus bicornis, 986; vomiting of, 242.
Prendergast, F. A., a new typhoid fever test, 1325.
Prescriptions, old and new, 26.
Press, the, and crime, 602; the, and suicide, 602.
Preston, J. W., mental stress a possible etiological factor in certain cases of pellagra, 1128.
Privilege, physician's waiver of, 1208; waiver of, by patient as to one medical attendant does not admit the evidence of others, 557.
Proctoclysis, 786.
Proctoscope and sigmoidoscope, 586.
Prosecution, malicious, 657.

Prostate, cancer of, 1042, 1046; concretions and calculi of, 388; diseases of, 1090; enucleation of, 139; hypertrophy of, as determined by stricture of urethra, 1047; hypertrophy of, etiology, 690; obstruction of, 1046; obstruction due to, 69; suggestions concerning, 337.
Prostatectomy, 389; a new method of, 237; control of bladder after, 1243; remote results in, 538.
Prostitution, 26; prevention of, 440.
Protein, low diet of, merits of, 529; requirement of, 1242.
Pruritus ani, 1289.
Pseudofever in children, 690.
Pseudosclerosis, 904.
Psoriasis, vegetable diet in, 536.
Psychanalysis and correction of character, 859.
Psychasthenia, alcoholic, treated by psychotherapy, 1151.
Psychogenous affections which are not hysterical, 528.
Psychoneuroses, 489; prognosis of, 391.
Psychosis, Karsakoff's, 1336.
Psychoses, surgical, 780.
Psychotherapy, 786.
Ptomaine poisoning, 782.
Ptosis, abdominal, 439; congenital, of abdominal viscera in the child, 504; of abdominal organs, surgical treatment of, 104.
Pubiotomy, remote results of, 527.
Puerperium, autoinfection of, 538; infection of, hemolytic streptococcus in, 75; morbidity of, 448; sepsis of, vaccine treatment of, 886.
Pulmonary tuberculosis, 241; agglutination and precipitation in early diagnosis of, 925; and the kidneys, 1288; apex infection in, 862; appearing as a cardiac affection, 341; artificial pneumothorax in treatment of, 1041; carbolic acid injections in, 294; causes of death in, 696; class method in treatment of, 697; climatic treatment of, 985; combined vaccine therapy in, 1089; compensatory displacement of thoracic viscera in, 948; contagiousness of, 85; fate of cases of, discharged from sanatoria, 490; lecocytes in, 698, 885; mixed infection in, 1191; mineralization in the treatment of, 1236; pneumothorax in, 619; ophthalmo-reaction in, 1291; prevalence of, among sailors, 791; sanatorium treatment of, 332, 697; sunlight in treatment of, 24; the albumin reaction of the sputum in, 870; treatment of, based on theory that cause is lime starvation, 12; tuberculin treatment of, in dispensaries, 22; treated by deep muscular injections of mercuric succinimide, 1109; *x*-ray diagnosis of, 26.
Pulse, irregularities of, 28; venous retinal, 338.
Purgatives, protest against routine use of, 842.
Purpura, 1139; deafness following, 829.
Pyelography, 1046, 1200; and dilatation of kidney, 86; value of, 102.
Pyemia, portal, and hemorrhoids, 788.
Pylorus, and duodenum, benign stenosis of, 536; hypertrophic stenosis of, in infants, 253; obstruction, diagnosed by the newer methods, 1248; obstructions at, in infants, 108; stenosis of, 786.
Pyocyaneus, immunity, 293; infection and rabies, 142.
Pyonephrosis and prostatitis actinomycotica, 538.
Pyretogenics, 132.
Pyocyaneus infection and rabies, 142.
Pyorrhea alveolaris, 1037.

Q.

Quarantine, New York, attack on, 1180; model administration of, 1326; professional endorsement of, 1235.
Queen Anne, last illness of, 292.
Questions, hypothetical, must be warranted by testimony, 658.
Quinine, and urea hydrochloride as local anesthetic, 768; anesthesia in tonsil removal, 813; in urticaria, 789.

R.

Rabies, 1289; and pyocyaneus infection, 142; complications of, Pasteur treatment of, 308; control of, 1081; microscopic diagnosis of, 537; Pasteur treatment of, 680.
Race, degeneracy of, 585.
Rachitis, and tetany vasoconstrictor substance in serum of, 442; care of, in Italy, 1218; early stages of, 108.
Radioactive menthol and iodine, 242.
Radiotherapy, see *x*-rays.
Radium, action of, on healthy tissues, 583; emanation therapy, 489; emanations, in treatment of gout, 1243; in scleroderma, 30; in treatment of cancer and varicose ulcers, 1338; in treatment of cancer of digestive tract, 609; in treatment of giant cell sarcoma, 419; in treatment of sarcoma, 401; research and therapy, 533; therapy, present status of, 580.
Railway sanitation, 734.
